The Definition of Standard ML: 
Changes from Version 3

David Berry
Robin Milner

January 22, 1990

The definition of Standard ML published in book form [Robin Milner, Mads Tofte and Robert Harper, The Definition of Standard ML, MIT, 1990] contains some minor changes from Version 3 [this document]. Most of these were required to ensure the existence of principal signatures as claimed in Section 5.13. The others are minor syntactic clarifications.

In addition to these changes, the book also has a new preface which replaces the prefaces to the first three versions of the definition, and several minor changes to the presentation.

Line numbers and page numbers refer to Version 3. The page numbers in the book are more or less the same up to and including Page 35 of Version 3, and one greater thereafter.

Section 2.2.

Line 6: The \+ sign has been deleted from before 3.32E5.

Line 8: Printable characters are those numbered 33-126.

Line 16: The escape sequence \c is allowed for any c with number 64-95. The number of \c is 64 less than the number of c.

Section 2.8.

Page 9: An optional op is allowed before a longcon or a longexcon in an atomic pattern. This change also applies to Page 72 in Appendix B.
Section 4.9.

The text up to and excluding the last paragraph is replaced with the following:

A type structure \((\theta, CE)\) is well-formed if either \(CE = \{\}\), or \(\theta\) is a type name \(t\). (The latter case arises, with \(CE \neq \{\}\), in datatye declarations.) All type structures occurring in elaborations are assumed to be well-formed.

A type structure \((t, CE)\) is said to respect equality if, whenever \(t\) admits equality, then either \(t = \text{ref}\) (see Appendix C) or, for each \(CE(\text{con})\) of the form \(\forall \alpha^{(k)}.(\tau \rightarrow \alpha^{(k)}t)\), the type function \(\Lambda \alpha^{(k)}\cdot \tau\) also admits equality. (This ensures that the equality predicate \(=\) will be applicable to a constructed value \((\text{con}, v)\) of type \(\tau^{(k)}t\) only when it is applicable to the value \(v\) itself, whose type is \(\tau^{(k)}/\alpha^{(k)}\).) A type environment \(TE\) respects equality if all its type structures do so.

Let \(TE\) be a type environment, and let \(T\) be the set of type names \(t\) such that \((t, CE)\) occurs in \(TE\) for some \(CE \neq \{\}\). Then \(TE\) is said to maximise equality if (a) \(TE\) respects equality, and also (b) if any larger subset of \(T\) were to admit equality (without any change in the equality attribute of any type names not in \(T\)) then \(TE\) would cease to respect equality.

Section 4.10.

Rules 19 and 20 both have an extra premise, and the associated comment has changed:

\[
\begin{align*}
C \oplus TE \vdash \text{datbind} &\Rightarrow VE, TE & \forall (t, CE) \in \text{Ran} \, TE, \ t \notin (T \text{ of } C) \\
& \text{TE maximises equality} \\
C \vdash \text{datatye } \text{datbind} &\Rightarrow (VE, TE) \text{ in Env} \tag{19}
\end{align*}
\]

\[
\begin{align*}
C \oplus TE \vdash \text{datbind} &\Rightarrow VE, TE & \forall (t, CE) \in \text{Ran} \, TE, \ t \notin (T \text{ of } C) \\
C \oplus (VE, TE) \vdash \text{dec }\Rightarrow \ E & \text{TE maximises equality} \\
C \vdash \text{abstype } \text{datbind} \text{ with dec } \Rightarrow \text{Abs}(TE, E) \tag{20}
\end{align*}
\]

(19),(20) The side conditions express that the elaboration of each datatye binding generates new type names and that as many of these new names as possible admit equality. Adding \(TE\) to the context on the left of the \(\vdash\) captures the recursive nature of the binding.
Section 4.12.

The following initial paragraph has been added:

The notion of enrichment, $E \succ E'$, between environments $E = (SE, TE, VE, EE)$ and $E' = (SE', TE', VE', EE')$ is defined in Section 5.11. For the present section, $E \succ E'$ may be taken to mean $SE = SE' = \{\}, TE = TE', EE = EE'$, Dom$VE = DomVE'$ and, for each $id \in$ Dom$VE$, $VE(id) \succ VE'(id)$.

Section 5.5.

The following requirement has been added:

We also require that

1. In every sentence $A \vdash \text{phrase} \Rightarrow A'$ inferred by the rules given in Section 5.14, the assembly $\{A, A'\}$ is admissible.

2. In the special case of a sentence $B \vdash \text{sigexp} \Rightarrow S$, we further require that the assembly consisting of all semantic objects occurring in the entire inference of this sentence be admissible. This is important for the definition of principal signatures in Section 5.13.

Section 5.9.

The phrase “We claim that” has been replaced with “It can be shown that”.

Section 5.12.

The phrase “We claim that” has been replaced with “It can be shown that”.

Section 5.13.

This section has been completely replaced with the following:

The definitions in this section concern the elaboration of signature expressions; more precisely they concern inferences of sentences of the form $B \vdash \text{sigexp} \Rightarrow S$, where $S$ is a structure and $B$ is a basis. Recall, from Section 5.5, that the assembly of all semantic objects in such an inference must be admissible.

For any basis $B$ and any structure $S$, we say that $B$ covers $S$ if for every substructure $(m, E)$ of $S$ such that $m \in N$ of $B$:

1. For every structure identifier $\text{strid} \in \text{Dom} E$, $B$ contains a substructure $(m, E')$ with $m$ free and $\text{strid} \in \text{Dom} E'$

2. For every type constructor $\text{tycon} \in \text{Dom} E$, $B$ contains a substructure $(m, E')$ with $m$ free and $\text{tycon} \in \text{Dom} E'$
(This condition is not a consequence of consistency of \( \{B, S\} \); informally, it states that if \( S \) shares a substructure with \( B \), then \( S \) mentions no more components of the substructure than \( B \) does.)

We say that a signature \((N)S\) is principal for \( \text{sigexp} \) in \( B \) if, choosing \( N \) so that \((N \cap B) \cap N = \emptyset\),

1. \( B \) covers \( S \)

2. \( B \vdash \text{sigexp} \Rightarrow S \)

3. Whenever \( B \vdash \text{sigexp} \Rightarrow S' \), then \((N)S \geq S'\)

We claim that if \( \text{sigexp} \) elaborates in \( B \) to some structure covered by \( B \), then it possesses a principal signature in \( B \).

Analogous to the definition given for type environments in Section 4.9, we say that a semantic object \( A \) respects equality if every type environment occurring in \( A \) respects equality.

Now let us assume that \( \text{sigexp} \) possesses a principal signature \( \Sigma_0 = (N_0)S_0 \) in \( B \). We wish to define, in terms of \( \Sigma_0 \), another signature \( \Sigma \) which provides more information about the equality attributes of structures which will match \( \Sigma_0 \). To this end, let \( T_0 \) be the set of type names \( t \in N_0 \) which do not admit equality, and such that \((t, CE)\) occurs in \( S_0 \) for some \( CE \neq \{\} \). Then we say \( \Sigma \) is equality-principal for \( \text{sigexp} \) in \( B \) if

1. \( \Sigma \) respects equality

2. \( \Sigma \) is obtained from \( \Sigma_0 \) just by making as many members of \( T_0 \) admit equality as possible, subject to 1. above

It is easy to show that, if any such \( \Sigma \) exists, it is determined uniquely by \( \Sigma_0 \); moreover, \( \Sigma \) exists if \( \Sigma_0 \) itself respects equality.

Section 5.14.

The requirement that \((N)S\) be principal in Rule 65 (and the associated comment) has been changed to requiring that it be equality-principal.
The Definition of Standard ML
Version 3

Robert Harper       Robin Milner
Mads Tofte
Laboratory for Foundations of Computer Science
Department of Computer Science
University of Edinburgh
Edinburgh EH9 3JZ, Scotland

1 May 1989
Preface to Version 3

The need for this third Version of the definition of Standard ML has arisen because of the discovery of an error concerning signature matching. We have also taken the opportunity to make a number of minor changes as a consequence of comments and corrections which we received following the printing of Version 2. Most of the changes are just clarifications of the document. For instance the use of op has been clarified (see Section 2.6 and Figure 7); a piece about core language programs has been inserted (Section 8) and a piece about resolving ambiguities during parsing has been inserted (Appendix B). A complete list of changes, even the most trivial, is available from the authors on request. The few important changes are (with references referring to Version 3):

**Type Explication** (This is the most important change.) To ensure that given any signature \( \Sigma \) and any structure \( S \) there is at most one realisation via which \( S \) matches \( \Sigma \) (and that matching can be done by an algorithm which does not invoke higher order unification), the signature \( \Sigma \) is required to be *type-explicit*, see the new Section 5.8, page 33. Thus for example

```ml
signature SIG =
 sig
  type 'a t;
  val x: int t;
  datatype 'a t = C
end
```

is now an illegal signature declaration, since the specification which specifies the type constructor \( t \), used in the type of \( x \), is overridden by the specification of another type constructor \( t \).

**Consistency** The definition of consistency of type structures, which was mistakenly too restrictive, has been corrected (Section 5.2, page 32).

**Exceptions** Two new exceptions \( \text{Abs} \) and \( \text{Neg} \) have been introduced corresponding to the operations \( \text{abs} \) and \( - \).

**Character Set** Strings are assumed to be built out of characters drawn from an alphabet of 256 characters (see Section 2.2).

**Type Constraints** Type constraints on non-expansive expressions are allowed and do not make the expression expansive (Section 4.7, page 20). Thus the right-hand side of \( \text{val } x = \text{[]} : \text{\_a list} \) is non-expansive. Moreover, the function expression on the right-hand side of a recursive value binding is allowed to be constrained by type constraints (Section 2.9, page 8, last bullet).

Edinburgh, 1 May 1989

iii
Preface to Version 2

This second Version of the definition of Standard ML incorporates some corrections to Version 1 [16], and also some extensions. As far as the Core language is concerned, it is consistent with the informal description [15] as modified by [23] and [1].

Great care was taken to make Version 1 clear, accurate and complete, and great care has been taken to revise it in the same spirit. The language may undergo changes in the future, but we have adopted a very conservative policy keeping changes to a bare minimum. Any future Version of this document will indicate precisely how it differs from its predecessor.

We shall first list the the changes from Version 1 and then list the few parts of the language which are considered somewhat experimental. Readers not familiar with Version 1 may skip the following list of changes.

CHANGES

Unless otherwise stated, references refer to Version 2.

1. The title of the document has been changed from “The Semantics of Standard ML” to “The Definition of Standard ML” since the document defines the language, syntax as well as semantics.

2. Appendix E describing how ML evolved has been added, see page 80.

3. An Index and a list of references have been added, see pages 89 and 86.

4. As envisaged in the preface to Version 1, a uniform treatment of exceptions and constructors has been adopted. The idea is explained in [1]. The changes to the semantics are consistent with the changes detailed in [1].

5. A new section, Section 8, pages 62–63, defining the syntax and semantics of Programs has been added. In particular, the interactive nature of the language has been made explicit.

6. The “applied” functor forms (Version 1, Section 3.4) have been given the status of derived forms and moved to Appendix A, page 67, while the “pure” forms (Version 1, Section 3.6) have been moved to the grammar itself (Section 3.4, pages 12 and 14). This entails that functors can be applied to structure expressions as well as to declarations.

7. The Closure Restrictions on signature expressions and functors (Version 1, Section 3.7) have been relaxed, see Section 3.6 page 14.
8. A new section "Signature Matching" has been inserted in the static semantics for Modules, see page 35. In this, it is clarified that matching a structure against a signature is a combination of instantiation and enrichment. In addition, the definition of functor signature matching has been simplified using the notion of signature matching, see page 44.

9. A type discipline for polymorphic references and exceptions has been provided. To this end, a distinction between imperative and applicative type variables has been introduced (page 16), together with the notions of imperative types (page 19) and non-expansive expressions (page 20). The definition of instantiation of type schemes is modified so that imperative type variables are instantiated with imperative types only, and the definition of the closure operation is modified to distinguish between expansive and non-expansive expressions (page 21). The modified inference rules are: the rule for value declarations (rule 17, page 25); the rules for exception bindings (rules 31 and 32, page 27); and the rule for declarations as structure-level declarations (rule 57, page 37).

10. Rule 85 in Version 1 concerning type sharing was wrong. It did not allow sharing between a type and a datatype. The corrected rule (rule 89, page 41) allows such sharing. For two type structures to satisfy a sharing equation, their type names (or more generally, their type functions), must be the same; however, the rule now allows the one type structure to have an empty constructor environment and the other to have a non-empty constructor environment, in accordance with the general principle that different consistent "views" can coexist.

11. The treatment of explicit type variables has been changed so that the scope of explicit type variables can be given by syntactic rules, see Section 4.6 page 19. These rules replace the rules given in [15]. The latter depended on traversing the program text in a particular order and one could give examples where, for instance, the textual ordering of the components of a pair would be significant for the scoping. The new rules do not have this defect.

12. The treatment of abstype has been corrected. Let dec' be a declaration of the form abstype datbind with dec end and let tycon be a type constructor declared by datbind. If the elaboration of datbind makes tycon an equality type, then the equality on tycon can be used in the body, dec, but the equality is not exported outside dec'. In Version 1, the equality was "exported" unintentionally. Thus the definition of Abs is revised (page 22) and the inference rule for abstype has been changed (page 25).

13. The symbol # is introduced as a reserved word (page 3). Moreover, it is admitted in symbolic identifiers (page 4).
14. We use the term "constructor binding" instead of "datatype construction". The syntactic classes are renamed accordingly. For instance, a declaration of a single datatype now takes the form

```
datatype tyvarseq tycon = conbind
```

15. It has been clarified that the equality attributes of bound type variables in type functions are not significant (page 19), and that the equality attributes of bound type variables in type schemes are significant (page 19). To take an example, the two type declarations `type 'a t = 'a list` and `type 'a t = ''a list` are equivalent, but the two value specifications `val x: 'a -> 'a and val x: ''a -> ''a` are not.

16. The rule for functor signature expressions has been corrected, see rule 95, page 42. The result part of a functor signature resulting from the elaboration of a functor signature expression must be principal.

This concludes the list of changes from Version 1. We now list the few parts of the language that are considered somewhat experimental and where feedback from users is needed and encouraged.

- The derived forms of functors (Appendix A) are somewhat experimental. It is sometimes convenient to be able to apply a functor to, say, a single value or a single type, rather than demanding that functors be applied to structures only; on the other hand, having both forms in the language may result in programming mistakes.

- The type discipline for polymorphic references and exceptions in the present version is built on the system developed and proved sound by Tofte [29]. As Damas' system [8], it is built on the idea of a boolean attribute of type variables. David MacQueen has suggested a more refined discipline, currently implemented in the New Jersey compiler, where the binary attribute is replaced by a weakness level, which is a natural number. While the present type discipline is simpler to use and understand than the more refined scheme, experience may show that the simple scheme admits too few programs. Since programs that are admitted under the simple scheme are also admitted under the more refined scheme, it seems sensible to start out with the simple scheme. The New Jersey compiler is currently being modified to support both schemes.

- No syntax has yet been added to the language which dictates exactly where functor specifications may be used. However, it is envisaged that if a compiler is asked to separately compile a functor $g$ which makes reference to a functor identifier $f$, then the compiler will demand a specification for $f$. Moreover, it is envisaged that the compiled $g$ should only be imported into a
basis if that basis contains a functor $f$ which matches the given specification according to the definition given in Section 5.15, page 44.

Edinburgh, 1 August 1988
Preface to Version 1

Great care has been taken to make this document clear, accurate and complete. Despite this we have called it "Version 1", since we expect to amend it for various reasons.

First, neither the greatest clarity nor the greatest accuracy is possible in a document of this complexity without feedback from readers. We therefore encourage readers to send us suspected errors, and to indicate points which are not clear to them. Although we do not intend to turn this document a pedagogic exposition, we shall willingly add short illuminating comments.

Second, the design of ML Modules – particularly the grammar – is still somewhat experimental, even though it is considerably refined from its original form. As a result of experimental use it may be changed or extended, and these changes or extensions will be defined in later versions of the present document.

Third, though the ML Core Language is more stable – simply because it has been subjected to more experiment – changes here may also occur. Wherever possible they will be "upwards compatible" – that is, the validity and semantics of existing programs will be preserved. One change is at present under discussion, and (for reasons of human resource) we are not delaying the issue of this document to include it. The proposed change is to the exception facility; it will not only add power but will also simplify the language – in particular, it will unite the notions of handler and match. This simplification is so significant that it deserves consideration even though it slightly violates the principle of upwards compatible change. But if it is adopted it will be possible to automate the necessary small modifications to existing programs.

Version 1 treats the ML Core Language and its Input/Output facilities as defined in Standard ML by Robert Harper, David MacQueen and Robin Milner (Report ECS-LFCS-86-2, Edinburgh University, Computer Science Department), but incorporating the changes defined in Changes to the Standard ML Core Language by Robin Milner (Report ECS-LFCS-87-33). As explained above, the Modules part of the language described here is considerably refined from that presented by MacQueen in ECS-LFCS-86-2.

Any future Version of this document will indicate precisely how it differs from its predecessor.

1 Introduction

This document formally defines Standard ML.

To understand the method of definition, at least in broad terms, it helps to consider how an implementation of ML is naturally organised. ML is an interactive language, and a program consists of a sequence of top-level declarations; the execution of each declaration modifies the top-level environment, which we call a basis, and reports the modification to the user.

In the execution of a declaration there are three phases: parsing, elaboration, and evaluation. Parsing determines the grammatical form of a declaration. Elaboration, the static phase, determines whether it is well-typed and well-formed in other ways, and records relevant type or form information in the basis. Finally evaluation, the dynamic phase, determines the value of the declaration and records relevant value information in the basis. Corresponding to these phases, our formal definition divides into three parts: grammatical rules, elaboration rules, and evaluation rules. Furthermore, the basis is divided into the static basis and the dynamic basis; for example, a variable which has been declared is associated with a type in the static basis and with a value in the dynamic basis.

In an implementation, the basis need not be so divided. But for the purpose of formal definition, it eases presentation and understanding to keep the static and dynamic parts of the basis separate. This is further justified by programming experience. A large proportion of errors in ML programs are discovered during elaboration, and identified as errors of type or form, so it follows that it is useful to perform the elaboration phase separately. In fact, elaboration without evaluation is just what is normally called compilation; once a declaration (or larger entity) is compiled one wishes to evaluate it – repeatedly – without re-elaboration, from which it follows that it is useful to perform the evaluation phase separately.

A further factoring of the formal definition is possible, because of the structure of the language. ML consists of a lower level called the Core language (or Core for short), a middle level concerned with programming-in-the-large called Modules, and a very small upper level called Programs. With the three phases described above, there is therefore a possibility of nine components in the complete language definition. We have allotted one section to each of these components, except that we have combined the parsing, elaboration and evaluation of Programs in one section. The scheme for the ensuing seven sections is therefore as follows:

<table>
<thead>
<tr>
<th>Syntax</th>
<th>Modules</th>
<th>Programs</th>
</tr>
</thead>
<tbody>
<tr>
<td>Core</td>
<td>Section 2</td>
<td>Section 3</td>
</tr>
<tr>
<td>Static Semantics</td>
<td>Section 4</td>
<td>Section 5</td>
</tr>
<tr>
<td>Dynamic Semantics</td>
<td>Section 6</td>
<td>Section 7</td>
</tr>
<tr>
<td>Programs</td>
<td>Section 8</td>
<td></td>
</tr>
</tbody>
</table>

The Core provides many phrase classes, for programming convenience. But about half of these classes are derived forms, whose meaning can be given by translation into the other half which we call the Bare language. Thus each of
the three parts for the Core treats only the bare language; the derived forms
are treated in Appendix A. This appendix also contains a few derived forms for
Modules. A full grammar for the language is presented in Appendix B.

In Appendices C and D the initial basis is detailed. This basis, divided into
its static and dynamic parts, contains the static and dynamic meanings of all
predefined identifiers.

The semantics is presented in a form known as Natural Semantics. It consists
of a set of rules allowing sentences of the form

\[ A \vdash \text{phrase} \Rightarrow A' \]

to be inferred, where \( A \) is often a basis (static or dynamic) and \( A' \) a semantic
object – often a type in the static semantics and a value in the dynamic semantics.
One should read such a sentence as follows: "in the basis \( A \), the phrase \( \text{phrase} \)
elaborates – or evaluates – to the object \( A' \)." Although the rules themselves
are formal the semantic objects, particularly the static ones, are the subject of a
mathematical theory which is presented in a succinct form in the relevant sections.
This theory, particularly the theory of types and signatures, will benefit from a
more pedagogic treatment in other publications; the treatment here is probably
the minimum required to understand the meaning of the rules.

The robustness of the semantics depends upon theorems. Some of these are
stated but not proved; others are presented as "claims" rather than theorems –
often they have been proved for a skeletal language, and although we are confident
of their truth their proofs in the context of the full language will present an
interesting challenge to a computer-assisted proof methodology, to attain complete
certainty.
2 Syntax of the Core

2.1 Reserved Words

The following are the reserved words used in the Core. They may not (except =) be used as identifiers. In this document the alphabetic reserved words are always shown in typewriter font.

```
abstype and andalso as case do datatype else
end exception fn fun handle if in infix
infixr let local nonfix of op open orelse
raise rec then type val with withtype while
( ) [ ] { } , : ; ... _ | = => -> #
```

2.2 Special constants

An integer constant is any non-empty sequence of digits, possibly preceded by a negation symbol (!). A real constant is an integer constant, possibly followed by a point (.) and one or more digits, possibly followed by an exponent symbol E and an integer constant; at least one of the optional parts must occur, hence no integer constant is a real constant. Examples: 0.7 +3.32E5 3E-7. Non-examples: 23 .3 4.E5 1E2.0.

A string constant is a sequence, between quotes ("), of zero or more printable characters, spaces or escape sequences. We assume an underlying alphabet of 256 different characters (numbered 0 to 255) which is such that the characters with numbers 0 to 127 coincide with the ASCII character set. Each escape sequence is introduced by the escape character \, and stands for a character sequence. The allowed escape sequences are as follows (all other uses of \ being incorrect):

```
\n   A single character interpreted by the system as end-of-line.
\t   Tab.
\c   The control character c, for any appropriate c.
\ddd The single character with number ddd (3 decimal digits denoting an integer in the interval [0,255]).
\"   "
\\   \n\l   \f   This sequence is ignored, where f:\f stands for a sequence of one or more formatting characters.
```

The formatting characters are a subset of the non-printable characters including at least space, tab, newline, formfeed. The last form allows long strings to be written on more than one line, by writing \ at the end of one line and at the start of the next.

We denote the class of special constants by SCon, and we shall use scon to range over SCon.
2.3 Comments

A comment is any character sequence within comment brackets (\*) in which comment brackets are properly nested. An unmatched comment bracket should be detected by the compiler.

2.4 Identifiers

The classes of identifiers for the Core are shown in Figure 1. We use var, tyvar to range over Var, TyVar etc. For each class X marked "long" there is a class longX of long identifiers; if x ranges over X then longx ranges over longX. The syntax of these long identifiers is given by the following:

\[
\begin{align*}
\text{longx} & \ ::= \ x \quad \text{identifier} \\
\text{strid}_1 \cdots \text{strid}_n \cdot \text{x} & \quad \text{qualified identifier} \ (n \geq 1)
\end{align*}
\]

The qualified identifiers constitute a link between the Core and the Modules. Throughout this document, the term "identifier", occurring without an adjective, refers to non-qualified identifiers only.

An identifier is either alphanumeric: any sequence of letters, digits, primes (') and underbars (_) starting with a letter or prime, or symbolic: any non-empty sequence of the following symbols

! % & $ # + - / : < = > ? @ \ ^ _ ` | *

In either case, however, reserved words are excluded. This means that for example # and | are not identifiers, but ## and |=| are identifiers. The only exception to this rule is that the symbol =, which is a reserved word, is also allowed as an identifier to stand for the equality predicate. The identifier = may not be re-bound; this precludes any syntactic ambiguity.

A type variable tyvar may be any alphanumeric identifier starting with a prime; the subclass EtyVar of TyVar, the equality type variables, consists of those which start with two or more primes. The subclass ImpTyVar of TyVar, the imperative type variables, consists of those which start with one or two primes followed by an underbar. The complement AppTyVar = TyVar \ ImpTyVar consists of the applicative type variables. The other six classes (Var, Con, ExCon, TyCon, Lab and StrId) are represented by identifiers not starting with a prime. However, * is
2.5 Lexical analysis

excluded from TyCon, to avoid confusion with the derived form of tuple type (see Figure 22). The class Lab is extended to include the numeric labels 1 2 3 ..., i.e. any numeral not starting with 0.

TyVar is therefore disjoint from the other six classes. Otherwise, the syntax class of an occurrence of identifier id in a Core phrase (ignoring derived forms, Section 2.7) is determined thus:

1. Immediately before "." – i.e. in a long identifier – or in an open declaration, id is a structure identifier. The following rules assume that all occurrences of structure identifiers have been removed.

2. At the start of a component in a record type, record pattern or record expression, id is a record label.

3. Elsewhere in types id is a type constructor, and must be within the scope of the type binding or datatype binding which introduced it.

4. Elsewhere, id is an exception constructor if it occurs in the scope of an exception binding which introduces it as such, or a value constructor if it occurs in the scope of a datatype binding which introduced it as such; otherwise it is a value variable.

It follows from the last rule that no value declaration can make a “hole” in the scope of a value or exception constructor by introducing the same identifier as a variable; this is because, in the scope of the declaration which introduces id as a value or exception constructor, any occurrence of id in a pattern is interpreted as the constructor and not as the binding occurrence of a new variable.

By means of the above rules a parser can determine the class to which each identifier class belongs; for the remainder of this document we shall therefore assume that the classes are all disjoint.

2.5 Lexical analysis

Each item of lexical analysis is either a reserved word, a numeric label, a special constant or a long identifier. Comments and formatting characters separate items (except within string constants; see Section 2.2) and are otherwise ignored. At each stage the longest next item is taken.

2.6 Infixed operators

An identifier may be given infix status by the infix or infixr directive, which may occur as a declaration; this status only pertains to its use as a var, a con or an excon within the scope (see below) of the directive. (Note that qualified identifiers never have infix status.) If id has infix status, then "exp₁ id exp₂" (resp. "pat₁ id pat₂") may occur – in parentheses if necessary – wherever the application
"id\{1=exp_1, 2=exp_2\}" or its derived form "id(exp_1, exp_2)" (resp "id(pat_1, pat_2)") would otherwise occur. On the other hand, an occurrence of any long identifier (qualified or not) prefixed by op is treated as non-infixed. The only required use of op is in prefixing a non-infixed occurrence of an identifier id which has infix status; elsewhere op, where permitted, has no effect. Infix status is cancelled by the nonfix directive. We refer to the three directives collectively as fixity directives.

The form of the fixity directives is as follows \((n \geq 1)\):

\[
\text{infix } (d) \ id_1 \ldots id_n \\
\text{infixr } (d) \ id_1 \ldots id_n \\
\text{nonfix } id_1 \ldots id_n 
\]

where \((d)\) is an optional decimal digit \(d\) indicating binding precedence. A higher value of \(d\) indicates tighter binding; the default is 0. infix and infixr dictate left and right associativity respectively; association is always to the left for different operators of the same precedence. The precedence of infix operators relative to other expression and pattern constructions is given in Appendix B.

The scope of a fixity directive \(dir\) is the ensuing program text, except that if \(dir\) occurs in a declaration \(dec\) in either of the phrases

\[
\text{let } dec \text{ in } \ldots \text{ end} \\
\text{local } dec \text{ in } \ldots \text{ end}
\]

then the scope of \(dir\) does not extend beyond the phrase. Further scope limitations are imposed for Modules.

These directives and \(op\) are omitted from the semantic rules, since they affect only parsing.

2.7 Derived Forms

There are many standard syntactic forms in ML whose meaning can be expressed in terms of a smaller number of syntactic forms, called the bare language. These derived forms, and their equivalent forms in the bare language, are given in Appendix A.

2.8 Grammar

The phrase classes for the Core are shown in Figure 2. We use the variable \(atexp\) to range over AtExp, etc.

The grammatical rules for the Core are shown in Figures 3 and 4.
2.8 Grammar

\begin{itemize}
\item AtExp \hspace{1cm} \text{atomic expressions}
\item ExpRow \hspace{1cm} \text{expression rows}
\item Exp \hspace{1cm} \text{expressions}
\item Match \hspace{1cm} \text{matches}
\item Mrule \hspace{1cm} \text{match rules}
\item Dec \hspace{1cm} \text{declarations}
\item ValBind \hspace{1cm} \text{value bindings}
\item TypBind \hspace{1cm} \text{type bindings}
\item DatBind \hspace{1cm} \text{datatype bindings}
\item ConBind \hspace{1cm} \text{constructor bindings}
\item ExBind \hspace{1cm} \text{exception bindings}
\item AtPat \hspace{1cm} \text{atomic patterns}
\item PatRow \hspace{1cm} \text{pattern rows}
\item Pat \hspace{1cm} \text{patterns}
\item Ty \hspace{1cm} \text{type expressions}
\item TyRow \hspace{1cm} \text{type-expression rows}
\end{itemize}

\textbf{Figure 2: Core Phrase Classes}

The following conventions are adopted in presenting the grammatical rules, and in their interpretation:

- The brackets \( \langle \rangle \) enclose optional phrases.

- For any syntax class \( X \) (over which \( x \) ranges) we define the syntax class \( X\text{seq} \) (over which \( x\text{seq} \) ranges) as follows:

\[
x\text{seq} ::= x \quad \text{(singleton sequence)}
\]
\[
\quad \quad \quad \quad (\text{empty sequence})
\]
\[
\quad \quad \quad \quad (x_1,\ldots,x_n) \quad \text{(sequence, } n \geq 1\text{)}
\]

(Note that the "\( \cdots \)" used here, meaning syntactic iteration, must not be confused with "\( \ldots \)" which is a reserved word of the language.)

- Alternative forms for each phrase class are in order of decreasing precedence; this resolves ambiguity in parsing, as explained in Appendix B.

- \( L \) (resp. \( R \)) means left (resp. right) association.

- The syntax of types binds more tightly than that of expressions.

- Each iterated construct (e.g. \textit{match}, \( \cdots \)) extends as far right as possible; thus, parentheses may be needed around an expression which terminates with a match, e.g. \textit{fn match}, if this occurs within a larger match.
\[ atexp ::= \begin{align*}
& scon \\
& \langle op \rangle longvar \\
& \langle op \rangle longcon \\
& \langle op \rangle longexcon \\
& \{ \langle exprow \rangle \} \\
& \text{let } dec \text{ in } exp \text{ end} \\
& (\exp)
\end{align*} \]

\[ exprow ::= \begin{align*}
& \text{lab} = \exp (, \exprow)
\end{align*} \]

\[ \begin{align*}
exp & ::= atexp \\
& exp \ application \ (L) \\
& \exp_1 \ id \ \exp_2 \\
& \exp : \ ty \\
& \exp \ handle \ match \\
& \text{raise } \exp \\
& \text{fn } match
\end{align*} \]

\[ \begin{align*}
match & ::= \text{mrule} (\mid \ \text{match}) \\
\text{mrule} & ::= \text{pat} \Rightarrow \exp \\
\text{dec} & ::= \text{val valbind} \\
& \text{type typbind} \\
& \text{datatype datbind} \\
& \text{abstype datbind with dec end} \\
& \text{exception exbind} \\
& \text{local } dec_1 \ \text{in } dec_2 \ \text{end} \\
& \text{open longstrid}_1 \ \cdots \ \text{longstrid}_n \\
& \text{dec}_1 (; \ dec_2 \\
& \text{infix } (d) \ id_1 \ \cdots \ id_n \\
& \text{infixr } (d) \ id_1 \ \cdots \ id_n \\
& \text{nonfix } id_1 \ \cdots \ id_n
\end{align*} \]

\[ \begin{align*}
\text{valbind} & ::= \text{pat} = \exp \langle \text{and valbind} \rangle \\
& \text{rec valbind} \\
\text{typbind} & ::= \text{tyvarseq tycon} = \ty \langle \text{and typbind} \rangle \\
\text{datbind} & ::= \text{tyvarseq tycon} = \conbind \langle \text{and datbind} \rangle \\
\text{conbind} & ::= \langle \text{op} \rangle \con (\of \ ty) (\mid \text{conbind}) \\
\text{exbind} & ::= \langle \text{op} \rangle \excon (\of \ ty) \langle \text{and exbind} \rangle \\
& \langle \text{op} \rangle \excon = \langle \text{op} \rangle \longexcon \langle \text{and exbind} \rangle
\end{align*} \]

Figure 3: Grammar: Expressions, Matches, Declarations and Bindings
2.9 Syntactic Restrictions

\[ atpat ::= - \quad \text{wildcard} \]
\[ scon \quad \text{special constant} \]
\[ (\text{op})\text{var} \quad \text{variable} \]
\[ \text{longcon} \quad \text{constant} \]
\[ \text{longexcon} \quad \text{exception constant} \]
\[ \{ \langle \text{patrow} \rangle \} \quad \text{record} \]
\[ (\text{pat} ) \quad \text{pattern row} \]
\[ patrow ::= \ldots \quad \text{wildcard} \]
\[ \text{lab} = \text{pat} (, \text{patrow}) \quad \text{pattern row} \]
\[ pat \]
\[ \text{atpat} \quad \text{atomic} \]
\[ (\text{op})\text{longcon atpat} \quad \text{value construction} \]
\[ (\text{op})\text{longexcon atpat} \quad \text{exception construction} \]
\[ \text{pat}_1 \text{ con } \text{pat}_2 \quad \text{infixed value construction} \]
\[ \text{pat}_1 \text{ excon } \text{pat}_2 \quad \text{infixed exception construction} \]
\[ \text{pat} : \text{ty} \quad \text{typed} \]
\[ (\text{op})\text{var}(,\text{ty}) \text{as pat} \quad \text{layered} \]
\[ ty ::= \text{tyvar} \quad \text{type variable} \]
\[ \{ \langle \text{tyrow} \rangle \} \quad \text{record type expression} \]
\[ \text{tyseq} \text{ longtycon} \quad \text{type construction} \]
\[ \text{ty} \rightarrow \text{ty}' \quad \text{function type expression (R)} \]
\[ (\text{ty}) \quad \text{type-expression row} \]

Figure 4: Grammar: Patterns and Type expressions

2.9 Syntactic Restrictions

- No pattern may contain the same \text{var} twice. No expression row, pattern row or type row may bind the same \text{lab} twice.

- No binding \text{valbind}, \text{typbind}, \text{datbind} or \text{exbind} may bind the same identifier twice; this applies also to value constructors within a \text{datbind}.

- In the left side \text{tyvarseq} \text{tycon} of any \text{typbind} or \text{datbind}, \text{tyvarseq} must not contain the same \text{tyvar} twice. Any \text{tyvar} occurring within the right side must occur in \text{tyvarseq}.

- For each value binding \text{pat} = \text{exp} within \text{rec}, \text{exp} must be of the form \text{fn match}, possibly constrained by one or more type expressions. The derived form of function-value binding given in Appendix A, page 67, necessarily obeys this restriction.
3 Syntax of Modules

For Modules there are further reserved words, identifier classes and derived forms. There are no further special constants; comments and lexical analysis are as for the Core. The derived forms for modules concern functors and appear in Appendix A.

3.1 Reserved Words

The following are the additional reserved words used in Modules.

\begin{itemize}
  \item eqtype
  \item functor
  \item include
  \item sharing
  \item sig
  \item signature
  \item struct
  \item structure
\end{itemize}

3.2 Identifiers

The additional syntax classes for Modules are SigId (signature identifiers) and FunId (functor identifiers); they may be either alphanumeric – not starting with a prime – or symbolic. The class of each identifier occurrence is determined by the grammatical rules which follow. Henceforth, therefore, we consider all identifier classes to be disjoint.

3.3 Infixed operators

In addition to the scope rules for fixity directives given for the Core syntax, there is a further scope limitation: if \texttt{dir} occurs in a structure-level declaration \texttt{strdec} in any of the phrases

\begin{itemize}
  \item \texttt{let strdec in \ldots end}
  \item \texttt{local strdec in \ldots end}
  \item \texttt{struct strdec end}
\end{itemize}

then the scope of \texttt{dir} does not extend beyond the phrase.

One effect of this limitation is that fixity is local to a generative structure expression – in particular, to such an expression occurring as a functor body. A more liberal scheme (which is under consideration) would allow fixity directives to appear also as specifications, so that fixity may be dictated by a signature expression; furthermore, it would allow an open or include construction to restore the fixity which prevailed in the structures being opened, or in the signatures being included. This scheme is not adopted at present.

3.4 Grammar for Modules

The phrase classes for Modules are shown in Figure 5. We use the variable \texttt{strexp} to range over StrExp, etc. The conventions adopted in presenting the grammatical rules for Modules are the same as for the Core. The grammatical rules are shown

Figure 5: Modules Phrase Classes

In Figures 6, 7 and 8.

It should be noted that functor specifications (FunSpec) cannot occur in programs; neither can the associated functor descriptions (FunDesc) and functor signature expressions (FunSigExp). The purpose of a *funspec* is to specify the static attributes (i.e. functor signature) of one or more functors. This will be useful, in fact essential, for separate compilation of functors. If, for example, a functor $g$ refers to another functor $f$ then — in order to compile $g$ in the absence of the declaration of $f$ — at least the specification of $f$ (i.e. its functor signature) must be available. At present there is no special grammatical form for a separately compilable “chunk” of text — which we may like to call call a *module* — containing a *fundec* together with a *funspec* specifying its global references. However, below in the semantics for Modules it is defined when a declared functor matches a functor signature specified for it. This determines exactly those functor environments (containing declared functors such as $f$) into which the separately compiled “chunk” containing the declaration of $g$ may be loaded.
3.5 Syntactic Restrictions

- No binding `strbind`, `sigbind`, or `funbind` may bind the same identifier twice.

- No description `valdesc`, `typdesc`, `datdesc`, `exdesc`, `strdesc` or `fundesc` may describe the same identifier twice; this applies also to value constructors within a `datdesc`. 
\[\begin{align*}
\text{spec} &::= \text{val valdesc} \\
&\quad \text{type typdesc} \\
&\quad \text{eqtype typdesc} \\
&\quad \text{datatype datdesc} \\
&\quad \text{exception exdesc} \\
&\quad \text{structure strdesc} \\
&\quad \text{sharing shareq} \\
&\quad \text{local spec}_1 \text{ in spec}_2 \text{ end} \\
&\quad \text{open longstrid}_1 \cdots \text{longstrid}_n \\
&\quad \text{include sigid}_1 \cdots \text{sigid}_n \\
\text{spec}_1 ( ; ) \text{ spec}_2
\end{align*}\]

\[\begin{align*}
\text{valdesc} &::= \text{var : ty} \text{ (and valdesc)} \\
\text{typdesc} &::= \text{tyvarseq tycon} \text{ (and typdesc)} \\
\text{datdesc} &::= \text{tyvarseq tycon = condesc} \text{ (and datdesc)} \\
\text{condesc} &::= \text{con (of ty) (| condesc)} \\
\text{exdesc} &::= \text{excon (of ty) (and exdesc)} \\
\text{strdesc} &::= \text{strid : sigexp (and strdesc)} \\
\text{shareq} &::= \text{longstrid}_1 = \cdots = \text{longstrid}_n \\
\text{type longtycon}_1 = \cdots = \text{longtycon}_n \quad \text{type sharing} \\
\text{shareq}_1 \text{ and shareq}_2 \quad \text{multiple}
\end{align*}\]

Figure 7: Grammar: Specifications
fundec ::= functor funbind
    fundec \(1\langle ; \rangle fundec_2\)

funbind ::= funid \(\langle strid : sigexp \rangle (\langle : sigexp' \rangle = strexp\langle and funbind\rangle)\)

funsigexp ::= \(\langle strid : sigexp \rangle : sigexp'\) functor signature expression

funspec ::= functor fundesc
    funspec \(1\langle ; \rangle funspec_2\)

fundesc ::= funid funsigexp \(\langle and fundesc\rangle\)

topdec ::= strdec
    sigdec
    fundec

structure-level declaration
signature declaration
functor declaration

Note: No topdec may contain, as an initial segment, a shorter top-level declaration followed by a semicolon.

Figure 8: Grammar: Functors and Top-level Declarations

3.6 Closure Restrictions

The semantics presented in later sections requires no restriction on reference to non-local identifiers. For example, it allows a signature expression to refer to external signature identifiers and (via sharing or open) to external structure identifiers; it also allows a functor to refer to external identifiers of any kind.

However, implementors who want to provide a simple facility for separate compilation may want to impose the following restrictions (ignoring references to identifiers bound in the initial basis \(B_0\), which may occur anywhere):

1. In any signature binding \(sigid = sigexp\), the only non-local references in \(sigexp\) are to signature identifiers.

2. In any functor description \(funid \langle strid : sigexp \rangle : sigexp'\), the only non-local references in \(sigexp\) and \(sigexp'\) are to signature identifiers, except that \(sigexp'\) may refer to \(strid\) and its components.

3. In any functor binding \(funid \langle strid : sigexp \rangle (\langle : sigexp' \rangle = strexp\), the only non-local references in \(sigexp, sigexp'\) and \(strexp\) are to functor and signature identifiers, except that both \(sigexp'\) and \(strexp\) may refer to \(strid\) and its components.

In the last two cases the final qualification allows, for example, sharing constraints to be specified between functor argument and result. (For a completely precise
3.6 Closure Restrictions

definition of these closure restrictions, see the comments to rules 66 (page 39), 91
(page 42) and 96 (page 42) in the static semantics of modules, Section 5.)

The significance of these restrictions is that they may ease separate compi-
lation; this may be seen as follows. If one takes a module to be a sequence of
signature declarations, functor specifications and functor declarations satisfying
the above restrictions then the elaboration of a module can be made to depend
on the initial static basis alone (in particular, it will not rely on structures outside
the module). Moreover, the elaboration of a module cannot create new free struc-
ture or type names, so name consistency (as defined in Section 5.2, page 32) is
automatically preserved across separately compiled modules. On the other hand,
imposing these restrictions may force the programmer to write many more shar-
ing equations than is needed if functors and signature expressions can refer to free
structures.
4 Static Semantics for the Core

Our first task in presenting the semantics – whether for Core or Modules, static or dynamic – is to define the objects concerned. In addition to the class of syntactic objects, which we have already defined, there are classes of so-called semantic objects used to describe the meaning of the syntactic objects. Some classes contain simple semantic objects; such objects are usually identifiers or names of some kind. Other classes contain compound semantic objects, such as types or environments, which are constructed from component objects.

4.1 Simple Objects

All semantic objects in the static semantics of the entire language are built from identifiers and two further kinds of simple objects: type constructor names and structure names. Type constructor names are the values taken by type constructors; we shall usually refer to them briefly as type names, but they are to be clearly distinguished from type variables and type constructors. Structure names play an active role only in the Modules semantics; they enter the Core semantics only because they appear in structure environments, which (in turn) are needed in the Core semantics only to determine the values of long identifiers. The simple object classes, and the variables ranging over them, are shown in Figure 9. We have included TyVar in the table to make visible the use of α in the semantics to range over TyVar.

\[
\begin{align*}
\alpha & \text{ or } tyvar \in TyVar & \text{type variables} \\
t & \in TyName & \text{type names} \\
m & \in StrName & \text{structure names}
\end{align*}
\]

Figure 9: Simple Semantic Objects

Each \( \alpha \in TyVar \) possesses a boolean equality attribute, which determines whether or not it admits equality, i.e. whether it is a member of EtyVar (defined on page 4). Independently hereof, each \( \alpha \) possesses a boolean attribute, the imperative attribute, which determines whether it is imperative, i.e. whether it is a member of ImpTyVar (defined on page 4) or not.

Each \( t \in TyName \) has an arity \( k \geq 0 \), and also possesses an equality attribute. We denote the class of type names with arity \( k \) by TyName\(^{(k)}\).

With each special constant scon we associate a type name type(scon) which is either int, real or string as indicated by Section 2.2.

4.2 Compound Objects

When \( A \) and \( B \) are sets Fin A denotes the set of finite subsets of \( A \), and \( A \twoheadrightarrow B \) denotes the set of finite maps (partial functions with finite domain) from \( A \) to \( B \).
The domain and range of a finite map, \( f \), are denoted \( \text{Dom} \ f \) and \( \text{Ran} \ f \). A finite map will often be written explicitly in the form \( \{ a_1 \mapsto b_1, \ldots, a_k \mapsto b_k \} \), \( k \geq 0 \); in particular the empty map is \( \{ \} \). We shall use the form \( \{ x \mapsto e \ ; \ \phi \} \) – a form of set comprehension – to stand for the finite map \( f \) whose domain is the set of values \( x \) which satisfy the condition \( \phi \), and whose value on this domain is given by \( f(x) = e \).

When \( f \) and \( g \) are finite maps the map \( f + g \), called \( f \) modified by \( g \), is the finite map with domain \( \text{Dom} \ f \cup \text{Dom} \ g \) and values

\[
(f + g)(a) = \begin{cases} 
\text{if } a \in \text{Dom} \ g & \text{then } g(a) \\
\text{else } f(a).
\end{cases}
\]

The compound objects for the static semantics of the Core Language are shown in Figure 10.

\[
\begin{align*}
\tau & \in \text{Type} = \text{TyVar} \cup \text{RecType} \cup \text{FunType} \cup \text{ConsType} \\
(\tau_1, \ldots, \tau_k) & \text{ or } \tau^{(k)} \in \text{Type}^k \\
(\alpha_1, \ldots, \alpha_k) & \text{ or } \alpha^{(k)} \in \text{TyVar}^k \\
\theta \text{ or } \Lambda\alpha^{(k)} & \in \text{Type} = \bigcup_{k \geq 0} \text{TyVar}^k \\
\sigma \text{ or } \forall\alpha^{(k)} & \in \text{Type} = \bigcup_{k \geq 0} \text{TyVar}^k \\
S \text{ or } (m, E) & \in \text{Str} = \text{Name} \times \text{Env} \\
(\theta, CE) & \in \text{TyStr} = \text{TyFcn} \times \text{ConEnv} \\
SE & \in \text{StrEnv} = \text{StrId} \Rightarrow \text{Str} \\
TE & \in \text{TyEnv} = \text{TyCon} \Rightarrow \text{TyStr} \\
CE & \in \text{ConEnv} = \text{Con} \Rightarrow \text{Type} \\
VE & \in \text{VarEnv} = \text{Var} \cup \text{Con} \cup \text{ExCon} \Rightarrow \text{Type} \\
EE & \in \text{ExConEnv} = \text{ExCon} \Rightarrow \text{Type} \\
E \text{ or } (SE, TE, VE, EE) & \in \text{Env} = \text{StrEnv} \times \text{TyEnv} \times \text{VarEnv} \times \text{ExConEnv} \\
T & \in \text{TyNameSet} = \text{Fin}(\text{TyName}) \\
U & \in \text{TyVarSet} = \text{Fin}(\text{TyVar}) \\
C \text{ or } T, U, E & \in \text{Context} = \text{TyNameSet} \times \text{TyVarSet} \times \text{Env}
\end{align*}
\]

Figure 10: Compound Semantic Objects

Note that \( \Lambda \text{ and } \forall \text{ bind type variables. For any semantic object } A \text{, tynames } A \) and \( \text{tyvars } A \) denote respectively the set of type names and the set of type variables occurring free in \( A \). Moreover, imptyvars \( A \) and apptyvars \( A \) denote respectively the set of imperative type variables and the set of applicative type variables occurring free in \( A \).
4.3 Projection, Injection and Modification

Projection: We often need to select components of tuples – for example, the variable-environment component of a context. In such cases we rely on variable names to indicate which component is selected. For instance "VE of E" means "the variable-environment component of E" and "m of S" means "the structure name of S".

Moreover, when a tuple contains a finite map we shall "apply" the tuple to an argument, relying on the syntactic class of the argument to determine the relevant function. For instance $C(tycon)$ means $(TE of C)tycon$.

A particular case needs mention: $C(con)$ is taken to stand for $(VE of C)con$; similarly, $C(excon)$ is taken to stand for $(VE of C)excon$. The type scheme of a value constructor is held in $VE$ as well as in $TE$ (where it will be recorded within a $CE$); similarly, the type of an exception constructor is held in $VE$ as well as in $EE$. Thus the re-binding of a constructor of either kind is given proper effect by accessing it in $VE$, rather than in $TE$ or in $EE$.

Finally, environments may be applied to long identifiers. For instance if $longcon = \text{strid}_1 \ldots \text{strid}_k$.con then $E(longcon)$ means

$$(VE of (SE of \cdots (SE of (SE of E)\text{strid}_1)\text{strid}_2 \cdots)\text{strid}_k)con.$$  

Injection: Components may be injected into tuple classes; for example, "VE in Env" means the environment $\{\}, \{\}, VE, \{\}$.

Modification: The modification of one map $f$ by another map $g$, written $f+g$, has already been mentioned. It is commonly used for environment modification, for example $E + E'$. Often, empty components will be left implicit in a modification; for example $E + VE$ means $E + (\{\}, \{\}, VE, \{\})$. For set components, modification means union, so that $C + (T, VE)$ means

$$( (T of C) \cup T, U of C, (E of C) + VE )$$  

Finally, we frequently need to modify a context $C$ by an environment $E$ (or a type environment $TE$ say), at the same time extending $T$ of $C$ to include the type names of $E$ (or of $TE$ say). We therefore define $C \oplus TE$, for example, to mean $C + (\text{tynames } TE, TE)$.

4.4 Types and Type functions

A type $\tau$ is an equality type, or admits equality, if it is of one of the forms

- $\alpha$, where $\alpha$ admits equality;

- $\{lab_1 \mapsto \tau_1, \ldots, lab_n \mapsto \tau_n\}$, where each $\tau_i$ admits equality;

- $\tau^{(k)}t$, where $t$ and all members of $\tau^{(k)}$ admit equality;
4.5 Type Schemes

- \( (\tau') \text{ref.} \)

A type function \( \theta = \Lambda \alpha^{(k)}.\tau \) has arity \( k \); it must be closed – i.e. \( \text{tyvars}(\tau) \subseteq \alpha^{(k)} \) – and the bound variables must be distinct. Two type functions are considered equal if they only differ in their choice of bound variables (alpha-conversion). In particular, the equality attribute has no significance in a bound variable of a type function; for example, \( \Lambda \alpha.\alpha \rightarrow \alpha \) and \( \Lambda \beta.\beta \rightarrow \beta \) are equal type functions even if \( \alpha \) admits equality but \( \beta \) does not. Similarly, the imperative attribute has no significance in the bound variable of a type function. If \( t \) has arity \( k \), then we write \( t \) to mean \( \Lambda \alpha^{(k)}.\alpha^{(k)}t \) (eta-conversion); thus \( \text{TyName} \subseteq \text{TypeFcn.} \) \( \theta = \Lambda \alpha^{(k)}.\tau \) is an equality type function, or admits equality, if when the type variables \( \alpha^{(k)} \) are chosen to admit equality then \( \tau \) also admits equality.

We write the application of a type function \( \theta \) to a vector \( \tau^{(k)} \) of types as \( \tau^{(k)} \theta \). If \( \theta = \Lambda \alpha^{(k)}.\tau \) we set \( \tau^{(k)} \theta = \tau^{(k)} / \alpha^{(k)} \) (beta-conversion).

We write \( \tau^{(k)} / \tau^{(k)} \) for the result of substituting type functions \( \theta^{(k)} \) for type names \( t^{(k)} \) in \( \tau \). We assume that all beta-conversions are carried out after substitution, so that for example

\[
(\tau^{(k)} t) / (\Lambda \alpha^{(k)}.\tau / \tau) = \tau^{(k)} / \alpha^{(k)}.
\]

A type is imperative if all type variables occurring in it are imperative.

4.5 Type Schemes

A type scheme \( \sigma = \forall \alpha^{(k)}.\tau \) generalises a type \( \tau' \), written \( \sigma \supset \tau' \), if \( \tau' = \tau^{(k)} / \alpha^{(k)} \) for some \( \tau^{(k)} \), where each member \( \tau_i \) of \( \tau^{(k)} \) admits equality if \( \alpha_i \) does, and \( \tau_i \) is imperative if \( \alpha_i \) is imperative. If \( \sigma' = \forall \beta^{(l)}.\tau' \) then \( \sigma \) generalises \( \sigma' \), written \( \sigma \supset \sigma' \), if \( \sigma \supset \tau' \) and \( \beta^{(l)} \) contains no free type variable of \( \sigma \). It can be shown that \( \sigma \supset \sigma' \) iff, for all \( \tau^{(n)} \), whenever \( \sigma' \supset \tau^{(n)} \) then also \( \sigma \supset \tau^{(n)} \).

Two type schemes \( \sigma \) and \( \sigma' \) are considered equal if they can be obtained from each other by renaming and reordering of bound type variables, and deleting type variables from the prefix which do not occur in the body. Here, in contrast to the case for type functions, the equality attribute must be preserved in renaming; for example \( \forall \alpha.\alpha \rightarrow \alpha \) and \( \forall \beta.\beta \rightarrow \beta \) are only equal if either both \( \alpha \) and \( \beta \) admit equality, or neither does. Similarly, the imperative attribute of a bound type variable of a type scheme is significant. It can be shown that \( \sigma = \sigma' \) iff \( \sigma \supset \sigma' \) and \( \sigma' \supset \sigma \).

We consider a type \( \tau \) to be a type scheme, identifying it with \( \forall().\tau \).

4.6 Scope of Explicit Type Variables

In the Core language, a type or datatype binding can explicitly introduce type variables whose scope is that binding. In the modules, a description of a value,
type, or datatype may contain explicit type variables whose scope is that description. However, we still have to account for the scope of an explicit type variable occurring in the "of ty" of a typed expression or pattern or in the "of ty" of an exception binding. For the rest of this section, we consider such occurrences of type variables only.

Every occurrence of a value declaration is said to scope a set of explicit type variables determined as follows.

First, an occurrence of α in a value declaration \texttt{val} \texttt{valbind} is said to be unguarded if the occurrence is not part of a smaller value declaration within \texttt{valbind}. In this case we say that \(\alpha\) occurs unguarded in the value declaration.

Then we say that \(\alpha\) is scoped at a particular occurrence \(O\) of \texttt{val} \texttt{valbind} in a program if (1) \(\alpha\) occurs unguarded in this value declaration, and (2) \(\alpha\) does not occur unguarded in any larger value declaration containing the occurrence \(O\).

Hence, associated with every occurrence of a value declaration there is a set \(U\) of the explicit type variables that are scoped at that occurrence. One may think of each occurrence of \texttt{val} as being implicitly decorated with such a set, for instance:

\begin{align*}
\texttt{val}_1 x &= (\text{let } \texttt{val}_1'(a) & Id1:'a \rightarrow 'a = \texttt{fn} z \rightarrow z \text{ in } Id1 \text{ Id1 } \text{ end}, \\
& \text{let } \texttt{val}_1'(a) & Id2:'a \rightarrow 'a = \texttt{fn} z \rightarrow z \text{ in } Id2 \text{ Id2 } \text{ end}) \\
\texttt{val}_2'(a) x &= (\text{let } \texttt{val}_1(a) & Id:'a \rightarrow 'a = \texttt{fn} z \rightarrow z \text{ in } Id \text{ Id } \text{ end}, \\
& \texttt{fn} z \rightarrow z'
\end{align*}

According to the inference rules in Section 4.10 the first example can be elaborated, but the second cannot since 'a is bound at the outer value declaration leaving no possibility of two different instantiations of the type of Id in the application Id Id.

4.7 Non-expansive Expressions

In order to treat polymorphic references and exceptions, the set \texttt{Exp} of expressions is partitioned into two classes, the \textit{expansive} and the \textit{non-expansive} expressions. Any variable, constructor and \texttt{fn} expression, possibly constrained by one or more type expressions, is non-expansive; all other expressions are said to be expansive. The idea is that the dynamic evaluation of a non-expansive expression will neither generate an exception nor extend the domain of the memory, while the evaluation of an expansive expression might.

4.8 Closure

Let \(\tau\) be a type and \(A\) a semantic object. Then \(\text{Clos}_A(\tau)\), the closure of \(\tau\) with respect to \(A\), is the type scheme \(\forall \alpha^{(k)}.\tau\), where \(\alpha^{(k)} = \text{tyvars}(\tau) \setminus \text{tyvars} A\). Commonly, \(A\) will be a context \(C\). We abbreviate the total closure \(\text{Clos}_C(\tau)\) to \(\text{Clos}(\tau)\). If the range of a variable environment \(VE\) contains only types (rather than arbi-
4.9 Type Environments and Well-formedness

(4.9) Type Environments and Well-formedness

A type environment takes the form

\[ TE = \{ tycon_i \mapsto (\theta_i, CE_i) ; 1 \leq i \leq k \} \]

and is well-formed if it satisfies the following conditions:

1. Either \( CE_i = \{ \} \), or \( \theta_i \) has the form \( t \) and each \( CE_i(con) \) has the form

   \[ \forall \alpha^{(k)}.(\tau \rightarrow \alpha^{(k)} t_i) \].

   The latter case occurs when \( tycon_i \) is a datatype constructor; it is conveniently distinguished from an ordinary type constructor by possessing at least one value constructor.

2. If \( tycon_i \) is a datatype constructor different from \( \text{ref} \), so that \( TE(tycon_i) = (t_i, CE_i) \) with \( CE_i \neq \{ \} \), then \( t_i \) admits equality only if, for each \( CE_i(con) = \forall \alpha^{(k)}.(\tau \rightarrow \alpha^{(k)} t_i) \), the type function \( \Lambda \alpha^{(k)}.\tau \) also admits equality. Furthermore, as many such \( t_i \) as possible admit equality, subject to the foregoing condition.

   This ensures that the equality predicate \( = \) will be applicable to a constructed value \( con(v) \) of type \( \tau^{(k)} t_i \) only when it is applicable to the value \( v \) itself, whose type is \( \tau^{(k)/\alpha^{(k)}} \).

3. Different datatype constructors are bound to different type names; i.e., if \( i \neq j \) and \( TE(tycon_i) = (t_i, CE_i) \) and \( \text{Dom} CE_i \neq \emptyset \) and \( TE(tycon_j) = (t_j, CE_j) \) and \( \text{Dom} CE_j \neq \emptyset \) then \( t_i \neq t_j \).
All type environments occurring in the rules are assumed well-formed. For any $TE$ of the form

$$TE = \{tycon_i \mapsto (t_i, CE_i) ; 1 \leq i \leq k\},$$

where no $CE_i$ is the empty map, and for any $E$ we define $\text{Abs}(E, TE)$ to be the environment obtained from $E$ and $TE$ as follows. First, let $\text{Abs}(TE)$ be the type environment $\{tycon_i \mapsto (t_i, \{\}) ; 1 \leq i \leq k\}$ in which all constructor environments $CE_i$ have been replaced by the empty map. (The effect of this first step is to convert each $tycon_i$ into an ordinary type constructor.) Let $t'_1, \ldots, t'_k$ be new distinct type names none of which admit equality. Then $\text{Abs}(E, TE)$ is the result of simultaneously substituting $t'_i$ for $t_i$, $1 \leq i \leq k$, throughout $E + \text{Abs}(TE)$. (The effect of this second step is to ensure that the use of equality on an abstype is restricted to the with part.)
4.10 Inference Rules

Each rule of the semantics allows inferences among sentences of the form

\[ A \vdash \text{phrase} \Rightarrow A' \]

where \( A \) is usually an environment or a context, \text{phrase} is a phrase of the Core, and \( A' \) is a semantic object – usually a type or an environment. It may be pronounced "\text{phrase} elaborates to \( A' \) in (context or environment) \( A \)". Some rules have extra hypotheses not of this form; they may be called side conditions.

In the presentation of the rules, phrases within single angle brackets \( \langle \rangle \) are called first options, and those within double angle brackets \( \langle\langle\rangle\rangle \) are called second options. To reduce the number of rules, we have adopted the following convention:

In each instance of a rule, the first options must be either all present or all absent; similarly the second options must be either all present or all absent.

Although not assumed in our definitions, it is intended that every context \( C = T, U, E \) has the property that tynames \( E \subseteq T \). Thus \( T \) may be thought of, loosely, as containing all type names which "have been generated". It is necessary to include \( T \) as a separate component in a context, since tynames \( E \) may not contain all the type names which have been generated; one reason is that a context \( T, \emptyset, E \) is a projection of the basis \( B = (M, T), F, G, E \) whose other components \( F \) and \( G \) could contain other such names – recorded in \( T \) but not present in \( E \). Of course, remarks about what "has been generated" are not precise in terms of the semantic rules. But the following precise result may easily be demonstrated:

Let \( S \) be a sentence \( T, U, E \vdash \text{phrase} \Rightarrow A \) such that tynames \( E \subseteq T \), and let \( S' \) be a sentence \( T', U', E' \vdash \text{phrase}' \Rightarrow A' \) occurring in a proof of \( S \); then also tynames \( E' \subseteq T' \).

Atomic Expressions

\[
C \vdash \text{atexp} \Rightarrow \tau
\]  

(1)

\[
C \vdash \text{scon} \Rightarrow \text{type(scon)}
\]

(2)

\[
C \vdash \text{longvar} \Rightarrow \tau
\]

\[
C \vdash \text{longvar} \Rightarrow \tau
\]

(3)

\[
C \vdash \text{longcon} \Rightarrow \tau
\]

(4)

\[
C \vdash \text{longexcon} = \tau
\]

\[
C \vdash \text{longexcon} \Rightarrow \tau
\]
\[ \{ C \vdash \text{exprow} \Rightarrow \varrho \} \]

\[ C \vdash \\{ \text{exprow} \} \Rightarrow \{ \varrho \} \text{ in Type} \]

\[ C \vdash \text{dec} \Rightarrow E \quad C \oplus E \vdash \text{exp} \Rightarrow \tau \]

\[ C \vdash \text{let} \text{ dec in exp end} \Rightarrow \tau \]

\[ C \vdash \text{exp} \Rightarrow \tau \]

\[ C \vdash (\text{exp}) \Rightarrow \tau \]

Comments:

(2),(3) The instantiation of type schemes allows different occurrences of a single longvar or longcon to assume different types.

(6) The use of \( \oplus \), here and elsewhere, ensures that type names generated by the first sub-phase are different from type names generated by the second sub-phase.

Expression Rows

\[ C \vdash \text{exp} \Rightarrow \tau \quad \{ C \vdash \text{exprow} \Rightarrow \varrho \} \]

\[ C \vdash \text{lab} = \text{exp} (, \text{exprow}) \Rightarrow \{ \text{lab} \mapsto \tau \} (\varrho) \]

Expressions

\[ C \vdash \text{atexp} \Rightarrow \tau \]

\[ C \vdash \text{atexp} \Rightarrow \tau \]

\[ C \vdash \text{exp} \Rightarrow \tau' \Rightarrow \tau \quad C \vdash \text{atexp} \Rightarrow \tau' \]

\[ C \vdash \text{exp atexp} \Rightarrow \tau \]

\[ C \vdash \text{exp} \Rightarrow \tau \quad C \vdash \text{ty} \Rightarrow \tau \]

\[ C \vdash \text{exp} : \text{ty} \Rightarrow \tau \]

\[ C \vdash \text{exp} \Rightarrow \tau \quad C \vdash \text{match} \Rightarrow \text{exn} \Rightarrow \tau \]

\[ C \vdash \text{handle} \text{ match} \Rightarrow \tau \]

\[ C \vdash \text{exn} \]

\[ C \vdash \text{raise} \text{ exp} \Rightarrow \tau \]

\[ C \vdash \text{match} \Rightarrow \tau \]

\[ C \vdash \text{fn} \text{ match} \Rightarrow \tau \]

Comments:

(9) The relational symbol \( \vdash \) is overloaded for all syntactic classes (here atomic expressions and expressions).
(11) Here $\tau$ is determined by $C$ and $ty$. Notice that type variables in $ty$ cannot be instantiated in obtaining $\tau$; thus the expression $1:\cdot$ will not elaborate successfully, nor will the expression $(\text{fn } x \Rightarrow x):\cdot$ $a \Rightarrow \cdot b$. The effect of type variables in an explicitly typed expression is to indicate exactly the degree of polymorphism present in the expression.

(13) Note that $\tau$ does not occur in the premise; thus a raise expression has "arbitrary" type.

**Matches**

$$
\frac{C \vdash \text{mrule} \Rightarrow \tau \quad (C \vdash \text{match} \Rightarrow \tau)}{C \vdash \text{mrule} \langle 1 \text{ match} \rangle \Rightarrow \tau}
$$

(15)

**Match Rules**

$$
\frac{C \vdash \text{pat} \Rightarrow (VE, \tau) \quad C + VE \vdash \text{exp} \Rightarrow \tau'}{C \vdash \text{pat} \Rightarrow \text{exp} \Rightarrow \tau \rightarrow \tau'}
$$

(16)

*Comment:* This rule allows new free type variables to enter the context. These new type variables will be chosen, in effect, during the elaboration of $\text{pat}$ (i.e., in the inference of the first hypothesis). In particular, their choice may have to be made to agree with type variables present in any explicit type expression occurring within $\text{exp}$ (see rule 11).

**Declarations**

$$
\frac{C + U \vdash \text{valbind} \Rightarrow VE \quad VE' = \text{Clos}_{C,\text{valbind}} VE \quad U \cap \text{tyvars} VE' = \emptyset}{C \vdash \text{val}_U \text{ valbind} \Rightarrow VE' \text{ in Env}}
$$

(17)

$$
\frac{C \vdash \text{typbind} \Rightarrow TE}{C \vdash \text{type typbind} \Rightarrow TE \text{ in Env}}
$$

(18)

$$
\frac{C \odot TE \vdash \text{datbind} \Rightarrow VE, TE \quad \forall (t, CE) \in \text{Ran} TE, \ t \notin (T \text{ of } C)}{C \vdash \text{datatype datbind} \Rightarrow (VE, TE) \text{ in Env}}
$$

(19)

$$
\frac{C \odot TE \vdash \text{datbind} \Rightarrow VE, TE \quad \forall (t, CE) \in \text{Ran} TE, \ t \notin (T \text{ of } C)}{C \odot (VE, TE) \vdash \text{dec} \Rightarrow E}
$$

$$
\frac{C \vdash \text{abstype datbind with dec end} \Rightarrow \text{Abs}(E, TE)}{C \vdash \text{exception exbind} \Rightarrow EE \quad VE = EE}
$$

(20)

$$
\frac{C \vdash \text{exbind} \Rightarrow EE \quad VE = EE}{C \vdash \text{exception exbind} \Rightarrow (VE, EE) \text{ in Env}}
$$

(21)
\[
\begin{align*}
& C \vdash \text{dec}_1 \Rightarrow E_1 \quad C \oplus E_1 \vdash \text{dec}_2 \Rightarrow E_2 \\
& C \vdash \text{local dec}_1 \; \text{in} \; \text{dec}_2 \; \text{end} \Rightarrow E_2 \\
& C(\text{longstrid}_1) = (m_1, E_1) \quad \ldots \quad C(\text{longstrid}_n) = (m_n, E_n) \\
& C \vdash \text{open} \; \text{longstrid}_1 \; \ldots \; \text{longstrid}_n \Rightarrow E_1 + \ldots + E_n \\
& C \vdash \Rightarrow \{\} \; \text{in} \; \text{Env} \\
& C \vdash \text{dec}_1 \Rightarrow E_1 \quad C \oplus E_1 \vdash \text{dec}_2 \Rightarrow E_2 \\
& C \vdash \text{dec}_1 \; (:) \; \text{dec}_2 \Rightarrow E_1 + E_2
\end{align*}
\]

Comments:

(17) Here \(VE\) will contain types rather than general type schemes. The closure of \(VE\) is exactly what allows variables to be used polymorphically, via rule 2.

Moreover, \(U\) is the set of explicit type variables scoped at this particular occurrence of \texttt{val valbind}, cf. Section 4.6, page 20. The side-condition on \(U\) ensures that these explicit type variables are bound by the closure operation. On the other hand, no other explicit type variable occurring free in \(VE\) will become bound, since it must be in \(U\) of \(C\), and is therefore excluded from closure by the definition of the closure operation (Section 4.8, page 21) since \(U\) of \(C \subseteq \text{tyvars} C\).

(19),(20) The side condition is the formal way of expressing that the elaboration of each datatype binding generates new type names. Adding \(TE\) to the context on the left of the \(\vdash\) captures the recursive nature of the binding. Recall that \(TE\) is assumed well-formed (as defined in Section 4.9). If \(\text{tymnames}(E \text{of } C) \subseteq T \text{ of } C\) and the side condition is satisfied then \(C \oplus TE\) is well-formed.

(20) The Abs operation was defined in Section 4.9, page 22.

(21) No closure operation is used here, since \(EE\) maps exception names to types rather than to general type schemes. Note that \(EE\) is also recorded in the \texttt{VarEnv} component of the resulting environment (see Section 4.3, page 18).

Value Bindings

\[
\begin{align*}
& C \vdash \text{valbind} \Rightarrow VE \\
& C \vdash \text{pat} \Rightarrow (VE, \tau) \quad C \vdash \text{exp} \Rightarrow \tau \quad (C \vdash \text{valbind} \Rightarrow VE') \\
& C \vdash \text{pat} = \text{exp} \; \text{(and valbind)} \Rightarrow VE \; (\Rightarrow VE') \\
& C + VE \vdash \text{valbind} \Rightarrow VE \\
& C \vdash \text{rec valbind} \Rightarrow VE
\end{align*}
\]

Comments:
(26) When the option is present we have Dom \(VE\) \(\cap\) Dom \(VE'\) = \(\emptyset\) by the syntactic restrictions.

(27) Modifying \(C\) by \(VE\) on the left captures the recursive nature of the binding. From rule 26 we see that any type scheme occurring in \(VE\) will have to be a type. Thus each use of a recursive function in its own body must be ascribed the same type.

**Type Bindings**

\[
\begin{align*}
\text{tyvarseq} = \alpha^{(k)} & \quad C \vdash ty \Rightarrow \tau & \quad \langle C \vdash \text{typbind} \Rightarrow TE \rangle \\
C \vdash \text{tyvarseq tycon} = ty \langle \text{and typbind} \rangle & \Rightarrow \\
\{tycon \mapsto (\Lambda \alpha^{(k)}, \tau, \{\})\} & \quad (+ TE)
\end{align*}
\]

(28)

*Comment:* The syntactic restrictions ensure that the type function \(\Lambda \alpha^{(k)}, \tau\) satisfies the well-formedness constraints of Section 4.4 and they ensure \(tycon \notin \text{Dom} TE\).

**Data Type Bindings**

\[
\begin{align*}
\text{tyvarseq} = \alpha^{(k)} & \quad C, \alpha^{(k)} t \vdash \text{conbind} \Rightarrow CE & \quad \langle C \vdash \text{datbind} \Rightarrow VE, TE \rangle \\
C \vdash \text{tyvarseq tycon} = \text{conbind} \langle \text{and datbind} \rangle & \Rightarrow \\
\text{Clos}CE(+VE), \{tycon \mapsto (t, \text{Clos}CE)\} & \quad (+ TE)
\end{align*}
\]

(29)

*Comment:* The syntactic restrictions ensure Dom \(VE \cap \text{Dom} CE = \emptyset\) and \(tycon \notin \text{Dom} TE\).

**Constructor Bindings**

\[
\begin{align*}
\langle C \vdash ty \Rightarrow \tau \rangle & \quad \langle \langle C, \tau \vdash \text{conbind} \Rightarrow CE \rangle \rangle
C, \tau \vdash \text{con} \langle \text{of ty} \rangle \langle \langle 1 \text{ conbind} \rangle \Rightarrow \\
\{\text{con} \mapsto \tau\} & \quad (+ \{\text{con} \mapsto \tau' \mapsto \tau\} \} \langle (+ CE)\rangle
\end{align*}
\]

(30)

*Comment:* By the syntactic restrictions \(\text{con} \notin \text{Dom} CE\).

**Exception Bindings**

\[
\begin{align*}
\langle C \vdash ty \Rightarrow \tau \quad \tau \text{ is imperative} \rangle & \quad \langle \langle C \vdash \text{exbind} \Rightarrow EE \rangle \rangle \\
C \vdash \text{excon} \langle \text{of ty} \rangle \langle \langle \text{and exbind} \rangle \Rightarrow \\
\{\text{excon} \mapsto \text{exn}\} & \quad (+ \{\text{excon} \mapsto \tau \mapsto \text{exn}\} \} \langle (+ EE)\rangle
\end{align*}
\]

(31)

\[
\begin{align*}
C(\text{longexcon}) = \tau & \quad \langle C \vdash \text{exbind} \Rightarrow EE \rangle \\
C \vdash \text{excon} = \text{longexcon} \langle \text{and exbind} \rangle & \Rightarrow \{\text{excon} \mapsto \tau\} \langle (+ EE)\rangle
\end{align*}
\]

(32)

*Comments:*
(31) Notice that $\tau$ must not contain any applicative type variables.

(31),(32) There is a unique $EE$, for each $C$ and $exbind$, such that $C \vdash exbind \Rightarrow EE$.

**Atomic Patterns**

\[
C \vdash \text{atpat} \Rightarrow (VE', \tau)
\]

(33) \[
C \vdash - \Rightarrow (\{\}, \tau)
\]

(34) \[
C \vdash scon \Rightarrow (\{\}, \text{type(scon)})
\]

(35) \[
C \vdash \text{var} \Rightarrow (\{\text{var} \mapsto \tau\}, \tau)
\]

(36) \[
C \vdash \text{longcon} \Rightarrow (\{\}, \tau^{(k)t})
\]

(37) \[
C \vdash \text{longexcon} = \text{exn}
\]

(38) \[
C \vdash \{\text{patrow} \Rightarrow (VE, \varrho)\} \Rightarrow (\{\} \langle + VE \rangle, \{\} \langle + \varrho \rangle \text{ in Type})
\]

(39) \[
C \vdash \text{pat} \Rightarrow (VE, \tau)
\]

\[
C \vdash (\text{pat}) \Rightarrow (VE, \tau)
\]

**Comments:**

(35) Note that $\text{var}$ can assume a type, not a general type scheme.

**Pattern Rows**

\[
C \vdash \text{patrow} \Rightarrow (VE, \varrho)
\]

(40) \[
C \vdash \ldots \Rightarrow (\{\}, \varrho)
\]

(41) \[
C \vdash \text{pat} \Rightarrow (VE, \tau) \quad (C \vdash \text{patrow} \Rightarrow (VE', \varrho) \quad \text{lab} \notin \text{Dom } \varrho) \quad C \vdash \text{lab} = \text{pat} (\ldots, \text{patrow}) \Rightarrow (VE \langle + VE' \rangle, \{(\text{lab} \mapsto \tau) \langle + \varrho \rangle\})
\]

**Comment:**

(41) By the syntactic restrictions, $\text{Dom } VE \cap \text{Dom } VE' = \emptyset$. 
4.10 Inference Rules

Patterns

\[ C \vdash \text{atpat} \Rightarrow (VE, \tau) \]
\[ C \vdash \text{atpat} \Rightarrow (VE, \tau) \]

\[ C(\text{longcon}) \vdash \tau' \rightarrow \tau \quad C \vdash \text{atpat} \Rightarrow (VE, \tau') \]
\[ C \vdash \text{longcon} \ \text{atpat} \Rightarrow (VE, \tau) \]  \hspace{1cm} (43)

\[ C(\text{longexcon}) = \tau \rightarrow \text{exn} \quad C \vdash \text{atpat} \Rightarrow (VE, \tau) \]
\[ C \vdash \text{longexcon} \ \text{atpat} \Rightarrow (VE, \text{exn}) \]  \hspace{1cm} (44)

\[ C \vdash \text{pat} \Rightarrow (VE, \tau) \quad C \vdash ty \Rightarrow \tau \]
\[ C \vdash \text{pat} : ty \Rightarrow (VE, \tau) \]  \hspace{1cm} (45)

\[ C \vdash \text{var} \Rightarrow (VE, \tau) \quad (C \vdash ty \Rightarrow \tau) \]
\[ C \vdash \text{pat} \Rightarrow (VE', \tau) \]
\[ C \vdash \text{var}(:: ty) \ 	ext{as pat} \Rightarrow (VE + VE', \tau) \]  \hspace{1cm} (46)

Comments:

(46) By the syntactic restrictions, DomVE \cap DomVE' = \emptyset.

Type Expressions

\[ \frac{\text{tyvar} = \alpha}{C \vdash \text{tyvar} \Rightarrow \alpha} \]  \hspace{1cm} (47)

\[ \frac{\langle C \vdash \text{tyrow} \Rightarrow \emptyset \rangle}{C \vdash \{\langle \text{tyrow} \rangle \} \Rightarrow \{\} \Rightarrow \emptyset \text{ in Type}} \]  \hspace{1cm} (48)

\[ \text{tyseq} = ty_1 \cdots ty_k \quad C \vdash ty_i \Rightarrow \tau_i \ (1 \leq i \leq k) \]
\[ C(\text{longtycon}) = (\emptyset, CE) \]
\[ C \vdash \text{tyseq} \ \text{longtycon} \Rightarrow \tau^{(k)} \theta \]  \hspace{1cm} (49)

\[ C \vdash ty \Rightarrow \tau \quad C \vdash ty' \Rightarrow \tau' \]
\[ C \vdash ty \rightarrow ty' \Rightarrow \tau \rightarrow \tau' \]  \hspace{1cm} (50)

\[ C \vdash ty \Rightarrow \tau \]
\[ C \vdash (\ ty ) \Rightarrow \tau \]  \hspace{1cm} (51)

Comments:

(49) Recall that for \(\tau^{(k)} \theta\) to be defined, \(\theta\) must have arity \(k\).
Type-expression Rows

\[
\frac{C \vdash ty \Rightarrow \tau \quad \{C \vdash \text{tyrow} \Rightarrow \varrho\}}{C \vdash \text{lab} : \text{ty} \ (\cdot \text{, tyrow}) \Rightarrow \{\text{lab} \mapsto \tau\}(\cdot \varrho)}
\]

(52)

Comment: The syntactic constraints ensure \( \text{lab} \notin \text{Dom} \varrho \).

4.11 Further Restrictions

There are a few restrictions on programs which should be enforced by a compiler, but are better expressed separately from the preceding Inference Rules. They are as follows:

1. For each occurrence of a record pattern containing a record wildcard, i.e. of the form \( \{\text{lab}_1 = \text{pat}_1, \ldots, \text{lab}_m = \text{pat}_m, \ldots\} \) the program context must determine uniquely the domain \( \{\text{lab}_1, \ldots, \text{lab}_n\} \) of its record type, where \( m \leq n \); thus, the context must determine the labels \( \{\text{lab}_{m+1}, \ldots, \text{lab}_n\} \) of the fields to be matched by the wildcard. For this purpose, an explicit type constraint may be needed. This restriction is necessary to ensure the existence of principal type schemes.

2. In a match of the form \( \text{pat}_1 \Rightarrow \text{exp}_1 \ | \cdots \ | \text{pat}_n \Rightarrow \text{exp}_n \) the pattern sequence \( \text{pat}_1, \ldots, \text{pat}_n \) should be irredundant; that is, each \( \text{pat}_j \) must match some value (of the right type) which is not matched by \( \text{pat}_i \) for any \( i < j \). In the context \( \text{fn} \text{match}, \) the \text{match} must also be exhaustive; that is, every value (of the right type) must be matched by some \( \text{pat}_i \). The compiler must give warning on violation of these restrictions, but should still compile the match. The restrictions are inherited by derived forms; in particular, this means that in the function binding \( \text{var} \ a\text{tpat}_1 \cdots \text{tpat}_n (\cdot \text{ty}) = \text{exp} \) (consisting of one clause only), each separate \( \text{tpat}_i \) should be exhaustive by itself.

4.12 Principal Environments

Let \( C \) be a context, and suppose that \( C \vdash \text{dec} \Rightarrow E \) according to the preceding Inference Rules. Then \( E \) is principal (for \( \text{dec} \) in the context \( C \)) if, for all \( E' \) for which \( C \vdash \text{dec} \Rightarrow E' \), we have \( E \triangleright E' \). We claim that if \( \text{dec} \) elaborates to any environment in \( C \) then it elaborates to a principal environment in \( C \). Strictly, we must allow for the possibility that type names which do not occur in \( C \), are chosen differently for \( E \) and \( E' \). Moreover, some imperative type variables may occur free in \( E \) without occurring free in \( C \). The stated claim is therefore made up to such variation.
5 Static Semantics for Modules

5.1 Semantic Objects

The simple objects for Modules static semantics are exactly as for the Core. The compound objects are those for the Core, augmented by those in Figure 11.

\[
\begin{align*}
M & \in \text{StrNameSet} = \text{Fin}(\text{StrName}) \\
N \text{ or } (M,T) & \in \text{NameSet} = \text{StrNameSet} \times \text{TyNameSet} \\
\Sigma \text{ or } (N)S & \in \text{Sig} = \text{NameSet} \times \text{Str} \\
\Phi \text{ or } (N)(S,(N')S') & \in \text{FunSig} = \text{NameSet} \times (\text{Str} \times \text{Sig}) \\
G & \in \text{SigEnv} = \text{SigId} \text{ fin } \text{Sig} \\
F & \in \text{FunEnv} = \text{FunId} \text{ fin } \text{FunSig} \\
B \text{ or } N,F,G,E & \in \text{Basis} = \text{NameSet} \times \text{FunEnv} \times \text{SigEnv} \times \text{Env}
\end{align*}
\]

Figure 11: Further Compound Semantic Objects

The prefix \((N)\), in signatures and functor signatures, binds both type names and structure names. We shall always consider a set \(N\) of names as partitioned into a pair \((M,T)\) of sets of the two kinds of name.

It is sometimes convenient to work with an arbitrary semantic object \(A\), or assembly \(A\) of such objects. As with the function \text{tynames}, \text{strnames}(A)\) and \text{names}(A)\) denote respectively the set of structure names and the set of names occurring free in \(A\).

Certain operations require a change of bound names in semantic objects; see for example Section 5.7. When bound type names are changed, we demand that all of their attributes (i.e. imperative, equality and arity) are preserved.

For any structure \(S = (m,(SE,TE,VE,EE))\) we call \(m\) the \text{structure name} or \text{name} of \(S\); also, the \text{proper substructures} of \(S\) are the members of Ran \(SE\) and their proper substructures. The \text{substructures} of \(S\) are \(S\) itself and its proper substructures. The structures \text{occurring in} an object or assembly \(A\) are the structures and substructures from which it is built.

The operations of projection, injection and modification are as for the Core. Moreover, we define \(C\) of \(B\) to be the context \((T\text{ of }B, \emptyset, E\text{ of }B)\), i.e. with an empty set of explicit type variables. Also, we frequently need to modify a basis \(B\) by an environment \(E\) (or a structure environment \(SE\) say), at the same time extending \(N\) of \(B\) to include the type names and structure names of \(E\) (or of \(SE\) say). We therefore define \(B \oplus SE\), for example, to mean \(B + \text{(names }SE,SE)\).
5.2 Consistency

A set of type structures is said to be consistent if, for all \((\theta_1, CE_1)\) and \((\theta_2, CE_2)\) in the set, if \(\theta_1 = \theta_2\) then

\[ CE_1 = \{\} \text{ or } CE_2 = \{\} \text{ or } \text{Dom } CE_1 = \text{Dom } CE_2 \]

A semantic object \(A\) or assembly \(A\) of objects is said to be consistent if (after changing bound names to make all nameset prefixes in \(A\) disjoint) for all \(S_1\) and \(S_2\) occurring in \(A\) and for every longstrid and every longtycon

1. If \(m\) of \(S_1 = m\) of \(S_2\), and both \(S_1(\text{longstrid})\) and \(S_2(\text{longstrid})\) exist, then

\[ m \text{ of } S_1(\text{longstrid}) = m \text{ of } S_2(\text{longstrid}) \]

2. If \(m\) of \(S_1 = m\) of \(S_2\), and both \(S_1(\text{longtycon})\) and \(S_2(\text{longtycon})\) exist, then

\[ \theta \text{ of } S_1(\text{longtycon}) = \theta \text{ of } S_2(\text{longtycon}) \]

3. The set of all type structures in \(A\) is consistent

As an example, a functor signature \((N)(S, (N')S')\) is consistent if, assuming first that \(N \cap N' = \emptyset\), the assembly \(A = \{S, S'\}\) is consistent.

We may loosely say that two structures \(S_1\) and \(S_2\) are consistent if \(\{S_1, S_2\}\) is consistent, but must remember that this is stronger than the assertion that \(S_1\) is consistent and \(S_2\) is consistent.

Note that if \(A\) is a consistent assembly and \(A' \subseteq A\) then \(A'\) is also a consistent assembly.

5.3 Well-formedness

Conditions for the well-formedness of type environments TE are given with the Core static semantics.

A signature \((N)S\) is well-formed if \(N \subseteq \text{names } S\), and also, whenever \((m, E)\) is a substructure of \(S\) and \(m \notin N\), then \(N \cap \text{(names } E) = \emptyset\). A functor signature \((N)(S, (N')S')\) is well-formed if \((N)S\) and \((N')S'\) are well-formed, and also, whenever \((m', E')\) is a substructure of \(S'\) and \(m' \notin N \cup N'\), then \((N \cup N') \cap \text{(names } E') = \emptyset\).

An object or assembly \(A\) is well-formed if every type environment, signature and functor signature occurring in \(A\) is well-formed.
5.4 Cycle-freedom

An object or assembly $A$ is cycle-free if it contains no cycle of structure names; that is, there is no sequence

$$m_0, \ldots, m_{k-1}, m_k = m_0 \ (k > 0)$$

of structure names such that, for each $i \ (0 \leq i < k)$ some structure with name $m_i$ occurring in $A$ has a proper substructure with name $m_{i+1}$.

5.5 Admissibility

An object or assembly $A$ is admissible if it is consistent, well-formed and cycle-free. Henceforth it is assumed that all objects mentioned are admissible; in particular, the admissibility of each semantic object mentioned is taken as a condition throughout the semantic rules which follow. (In our semantic description we have not undertaken to indicate how admissibility should be checked in an implementation.)

5.6 Type Realisation

A type realisation is a map $\varphi_{Ty} : \text{TyName} \rightarrow \text{TypeFcn}$ such that $t$ and $\varphi_{Ty}(t)$ have the same arity, and if $t$ admits equality then so does $\varphi_{Ty}(t)$.

The support $\text{Supp} \varphi_{Ty}$ of a type realisation $\varphi_{Ty}$ is the set of type names $t$ for which $\varphi_{Ty}(t) \neq t$.

5.7 Realisation

A realisation is a function $\varphi$ of names, partitioned into a type realisation $\varphi_{Ty} : \text{TyName} \rightarrow \text{TypeFcn}$ and a function $\varphi_{Str} : \text{StrName} \rightarrow \text{StrName}$. The support $\text{Supp} \varphi$ of a realisation $\varphi$ is the set of names $n$ for which $\varphi(n) \neq n$. The yield $\text{Yield} \varphi$ of a realisation $\varphi$ is the set of names which occur in some $\varphi(n)$ for which $n \in \text{Supp} \varphi$.

Realisations $\varphi$ are extended to apply to all semantic objects; their effect is to replace each name $n$ by $\varphi(n)$. In applying $\varphi$ to an object with bound names, such as a signature $(N)S$, first bound names must be changed so that, for each binding prefix $(N)$,

$$N \cap (\text{Supp} \varphi \cup \text{Yield} \varphi) = \emptyset.$$  

5.8 Type Explication

A signature $(N)S$ is type-explicit if, whenever $t \in N$ and occurs free in $S$, then some substructure of $S$ contains a type environment $TE$ such that $TE(\text{tycon}) = (t, CE)$ for some $\text{tycon}$ and some $CE$. 
5.9 Signature Instantiation

A structure \( S_2 \) is an instance of a signature \( \Sigma_1 = (N_1)S_1 \), written \( \Sigma_1 \geq S_2 \), if there exists a realisation \( \varphi \) such that \( \varphi(S_1) = S_2 \) and \( \text{Supp} \varphi \subseteq N_1 \). (Note that if \( \Sigma_1 \) is type-explicit then there is at most one such \( \varphi \).) A signature \( \Sigma_2 = (N_2)S_2 \) is an instance of \( \Sigma_1 = (N_1)S_1 \), written \( \Sigma_1 \geq \Sigma_2 \), if \( \Sigma_1 \geq S_2 \) and \( N_2 \cap (\text{names} \Sigma_1) = \emptyset \). We claim that \( \Sigma_1 \geq \Sigma_2 \) iff, for all \( S \), whenever \( \Sigma_2 \geq S \) then \( \Sigma_1 \geq S \).

5.10 Functor Signature Instantiation

A pair \( (S, (N')S') \) is called a functor instance. Given \( \Phi = (N_1)(S_1, (N'_1)S'_1) \), a functor instance \( (S_2, (N'_2)S'_2) \) is an instance of \( \Phi \), written \( \Phi \geq (S_2, (N'_2)S'_2) \), if there exists a realisation \( \varphi \) such that \( \varphi(S_1, (N'_1)S'_1) = (S_2, (N'_2)S'_2) \) and \( \text{Supp} \varphi \subseteq N_1 \).

5.11 Enrichment

In matching a structure to a signature, the structure will be allowed both to have more components, and to be more polymorphic, than (an instance of) the signature. Precisely, we define enrichment of structures, environments and type structures by mutual recursion as follows.

A structure \( S_1 = (m_1, E_1) \) enriches another structure \( S_2 = (m_2, E_2) \), written \( S_1 \succ S_2 \), if

1. \( m_1 = m_2 \)
2. \( E_1 \succ E_2 \)

An environment \( E_1 = (SE_1, TE_1, VE_1, EE_1) \) enriches another environment \( E_2 = (SE_2, TE_2, VE_2, EE_2) \), written \( E_1 \succ E_2 \), if

1. \( \text{Dom} SE_1 \supseteq \text{Dom} SE_2 \), and \( SE_1(\text{strid}) \succ SE_2(\text{strid}) \) for all \( \text{strid} \in \text{Dom} SE_2 \)
2. \( \text{Dom} TE_1 \supseteq \text{Dom} TE_2 \), and \( TE_1(\text{tycon}) \succ TE_2(\text{tycon}) \) for all \( \text{tycon} \in \text{Dom} TE_2 \)
3. \( \text{Dom} VE_1 \supseteq \text{Dom} VE_2 \), and \( VE_1(\text{id}) \succ VE_2(\text{id}) \) for all \( \text{id} \in \text{Dom} VE_2 \)
4. \( \text{Dom} EE_1 \supseteq \text{Dom} EE_2 \), and \( EE_1(\text{excon}) = EE_2(\text{excon}) \) for all \( \text{excon} \in \text{Dom} EE_2 \)

Finally, a type structure \( (\theta_1, CE_1) \) enriches another type structure \( (\theta_2, CE_2) \), written \( (\theta_1, CE_1) \succ (\theta_2, CE_2) \), if

1. \( \theta_1 = \theta_2 \)
2. Either \( CE_1 = CE_2 \) or \( CE_2 = \{\} \)
5.12 Signature Matching

A structure $S$ matches a signature $\Sigma_1$ if there exists a structure $S^- \prec S$. Thus matching is a combination of instantiation and enrichment. There is at most one such $S^-$, given $\Sigma_1$ and $S$. Moreover, writing $\Sigma_1 = (N_1)S_1$, if $\Sigma_1 \geq S^-$ then there exists a realisation $\varphi$ with $\text{Supp}\, \varphi \subseteq N_1$ and $\varphi(S_1) = S^-$. We shall then say that $S$ matches $\Sigma_1$ via $\varphi$. (Note that if $\Sigma_1$ is type-explicit then $\varphi$ is uniquely determined by $\Sigma_1$ and $S$.)

A signature $\Sigma_2$ matches a signature $\Sigma_1$ if for all structures $S$, if $S$ matches $\Sigma_2$ then $S$ matches $\Sigma_1$. We claim that $\Sigma_2 = (N_2)S_2$ matches $\Sigma_1 = (N_1)S_1$ if and only if there exists a realisation $\varphi$ with $\text{Supp}\, \varphi \subseteq N_1$ and $\varphi(S_1) \prec S_2$ and $N_2 \cap \text{names} \Sigma_1 = \emptyset$.

5.13 Principal Signatures

Let $B$ be a basis, and suppose that $B \vdash \text{sigexp} \Rightarrow S$ according to the rules below. Then $(N)S$ is principal (for $\text{sigexp}$ in the basis $B$) if $(\text{Nof } B) \cap N = \emptyset$, and for all $S'$ for which $B \vdash \text{sigexp} \Rightarrow S'$ we have $(N)S \succeq S'$. We claim that if $\text{sigexp}$ elaborates to any structure $S$ in $B$ then it possesses a principal signature in $B$. 
5.14 Inference Rules

As for the Core, the rules of the Modules static semantics allow sentences of the form

$$ A \vdash \text{phrase} \Rightarrow A' $$

to be inferred, where in this case $A$ is either a basis, a context or an environment and $A'$ is a semantic object. The convention for options is as in the Core semantics.

Although not assumed in our definitions, it is intended that every basis $B = N, F, G, E$ in which a $\text{topdec}$ is elaborated has the property that names $F \cup \text{names } G \cup \text{names } E \subseteq N$. This is not the case for bases in which signature expressions and specifications are elaborated, but the following Theorem can be proved:

Let $S$ be an inferred sentence $B \vdash \text{topdec} \Rightarrow B'$ in which $B$ satisfies the above condition. Then $B'$ also satisfies the condition.

Moreover, if $S'$ is a sentence of the form $B'' \vdash \text{phrase} \Rightarrow A$ occurring in a proof of $S$, where $\text{phrase}$ is either a structure expression or a structure-level declaration, then $B''$ also satisfies the condition.

Finally, if $T, U, E \vdash \text{phrase} \Rightarrow A$ occurs in a proof of $S$, where $\text{phrase}$ is a phrase of the Core, then $\text{tynames } E \subseteq T$.

**Structure Expressions**

$$B \vdash \text{strexpr} \Rightarrow S$$

\[
\begin{align*}
B \vdash \text{strdec} \Rightarrow E & \quad m \notin (\text{N of } B) \cup \text{names } E \\
B \vdash \text{struct } \text{strdec and } \Rightarrow (m, E) \\
B(\text{longstrid}) = S & \\
B \vdash \text{longstrid} \Rightarrow S
\end{align*}
\]

(53)

\[
\begin{align*}
B \vdash \text{strexpr} \Rightarrow S & \\
B(\text{funid}) \geq (S'', (N')S'), S \succeq S'' & \\
(N \text{ of } B) \cap N' = \emptyset & \\
B \vdash \text{funid } \text{strexpr } \Rightarrow S'
\end{align*}
\]

(55)

\[
\begin{align*}
B \vdash \text{strdec} \Rightarrow E & \quad B \oplus E \vdash \text{strexpr} \Rightarrow S \\
B \vdash \text{let } \text{strdec in } \text{strexpr end} \Rightarrow S
\end{align*}
\]

(56)

**Comments:**

(53) The side condition ensures that each generative structure expression receives a new name. If the expression occurs in a functor body the structure name will be bound by $(N')$ in rule 99; this will ensure that for each application of the functor, by rule 55, a new distinct name will be chosen for the structure generated.
(55) The side condition \((N \cap N') = \emptyset\) can always be satisfied by renaming bound names in \((N')S'\) thus ensuring that the generated structures receive new names.

Let \(B(funid) = (N)(S_f, (N')S'_f)\). Assuming that \((N)S_f\) is type-explicit, the realisation \(\varphi\) for which \(\varphi(S_f, (N')S'_f) = (S'', (N')S'')\) is uniquely determined by \(S\), since \(S \succ S''\) can only hold if the type names and structure names in \(S\) and \(S''\) agree. Recall that enrichment \(\succ\) allows more components and more polymorphism, while instantiation \(\geq\) does not.

Sharing between argument and result specified in the declaration of the functor \(funid\) is represented by the occurrence of the same name in both \(S_f\) and \(S'_f\), and this repeated occurrence is preserved by \(\varphi\), yielding sharing between the argument structure \(S\) and the result structure \(S'\) of this functor application.

(56) The use of \(\oplus\), here and elsewhere, ensures that structure and type names generated by the first sub-phrase are distinct from names generated by the second sub-phrase.

Structure-level Declarations

\[
\begin{gathered}
B \vdash strdec \Rightarrow E \\
\quad \frac{C \text{ of } B \vdash \text{dec } \Rightarrow E \quad E \text{ principal in } (C \text{ of } B)}{B \vdash \text{dec } \Rightarrow E} \quad (57) \\
\quad \frac{B \vdash \text{strbind } \Rightarrow SE}{B \vdash \text{structure strbind } \Rightarrow SE \text{ in Env}} \quad (58) \\
\quad \frac{B \vdash strdec_1 \Rightarrow E_1 \quad B \oplus E_1 \vdash strdec_2 \Rightarrow E_2}{B \vdash \text{local strdec}_1 \text{ in strdec}_2 \text{ end } \Rightarrow E_2} \quad (59) \\
\quad \quad \quad \frac{B \vdash \quad \Rightarrow \{\} \text{ in Env}}{} \quad (60) \\
\quad \frac{B \vdash strdec_1 \Rightarrow E_1 \quad B \oplus E_1 \vdash strdec_2 \Rightarrow E_2}{B \vdash strdec_1 \{;\} \text{ strdec}_2 \Rightarrow E_1 + E_2} \quad (61)
\end{gathered}
\]

Comments:

(57) The side condition ensures that all type schemes in \(E\) are as general as possible.
Structure Bindings

\[ B \vdash \text{strbind} \Rightarrow SE \]

\[ B \vdash \text{strexp} \Rightarrow S \quad \langle B \vdash \text{sigexp} \Rightarrow \Sigma, \Sigma \geq S', S \leftarrow S' \rangle \quad \langle \langle B + \text{names} S \vdash \text{strbind} \Rightarrow SE \rangle \rangle \]

\[ B \vdash \text{strid} \langle : \text{sigexp} \rangle = \text{strexp} \langle \langle \text{and strbind} \rangle \rangle \Rightarrow \{ \text{strid} \mapsto S'(') \} \langle \langle + SE \rangle \rangle \]  \hspace{1cm} (62)

Comment: If present, sigexp has the effect of restricting the view which strid provides of $S$ while retaining sharing of names. The notation $S'(\text{'})$ means $S'$, if the first option is present, and $S$ if not.

Signature Expressions

\[ B \vdash \text{spec} \Rightarrow E \]

\[ B \vdash \text{sig spec end} \Rightarrow (m, E) \]  \hspace{1cm} (63)

\[ B(\text{sigid}) \geq S \]

\[ B \vdash \text{sigid} \Rightarrow S \]  \hspace{1cm} (64)

Comments:

(63) In contrast to rule 53, $m$ is not here required to be new. The name $m$ may be chosen to achieve the sharing required in rule 88, or to achieve the enrichment side conditions of rule 62 or 99. The choice of $m$ must result in an admissible object.

(64) The instance $S$ of $B(\text{sigid})$ is not determined by this rule, but – as in rule 63 – the instance may be chosen to achieve sharing properties or enrichment conditions.

\[ B \vdash \text{sigexp} \Rightarrow \Sigma \]

\[ B \vdash \text{sigexp} \Rightarrow S \quad (N)S \text{ principal for sigexp in } B \]

\[ (N)S \text{ type-explicit} \]

\[ B \vdash \text{sigexp} \Rightarrow (N)S \]  \hspace{1cm} (65)

Comment: A signature expression sigexp which is an immediate constituent of a structure binding, a signature binding, a functor binding or a functor signature is elaborated to a principal and type-explicit signature, see rules 62, 69, 95 and 99. By contrast, signature expressions occurring in structure descriptions are elaborated to structures using the liberal rules 63 and 64, see rule 87, so that names can be chosen to achieve sharing, when necessary.
5.14 Inference Rules

Signature Declarations

\[ B \vdash \text{sigdec} \Rightarrow G \]

\[ B \vdash \text{signature} \Rightarrow G \]

\[ B \vdash \Rightarrow \{ \} \]

\[ B \vdash \text{sigdec}_1 \Rightarrow G_1 \quad B + G_1 \vdash \text{sigdec}_2 \Rightarrow G_2 \]

\[ B \vdash \text{sigdec}_1 (\cdot) \text{ sigdec}_2 \Rightarrow G_1 + G_2 \]

Comments:

(66) The first closure restriction of Section 3.6 can be enforced by replacing the \( B \) in the premise by \( B_0 + G \) of \( B \).

(68) A signature declaration does not create any new structures or types; hence the use of \( + \) instead of \( \oplus \).

Signature Bindings

\[ B \vdash \text{sigexp} \Rightarrow \Sigma \quad (B \vdash \text{sigbind} \Rightarrow G) \]

\[ B \vdash \text{sigid} = \text{sigexp} \text{ (and sigbind)} \Rightarrow \{ \text{sigid } \mapsto \Sigma \} \leftarrow G \]

Comment: The principality condition implicit in the first premise ensures that the signature found is as general as possible given the sharing constraints present in \( \text{sigexp} \).

Specifications

\[ B \vdash \text{spec} \Rightarrow E \]

\[ C \text{ of } B \vdash \text{valdesc} \Rightarrow VE \]

\[ B \vdash \text{val valdesc} \Rightarrow \text{ClosVE in Env} \]

\[ C \text{ of } B \vdash \text{typdesc} \Rightarrow TE \]

\[ B \vdash \text{type typdesc} \Rightarrow TE \text{ in Env} \]

\[ C \text{ of } B \vdash \text{typdesc} \Rightarrow TE \quad \forall (\theta, CE) \in \text{Ran TE}, \theta \text{ admits equality} \]

\[ B \vdash \text{eqtype typdesc} \Rightarrow TE \text{ in Env} \]

\[ C \text{ of } B + TE \vdash \text{datdesc} \Rightarrow VE, TE \]

\[ B \vdash \text{datatype datdesc} \Rightarrow (VE, TE) \text{ in Env} \]

\[ C \text{ of } B \vdash \text{exdesc} \Rightarrow EE \quad VE = EE \]

\[ B \vdash \text{exception exdesc} \Rightarrow (VE, EE) \text{ in Env} \]

\[ B \vdash \text{strdesc} \Rightarrow SE \]

\[ B \vdash \text{structure strdesc} \Rightarrow SE \text{ in Env} \]
\[
\frac{B \vdash \text{shareq } \Rightarrow \{\}}{B \vdash \text{sharing shareq } \Rightarrow \{\} \text{ in Env}} \tag{76}
\]
\[
\frac{B \vdash \text{spec} \Rightarrow E_1 \quad B + E_1 \vdash \text{spec}_2 \Rightarrow E_2}{B \vdash \text{local spec}_1 \text{ in spec}_2 \text{ end } \Rightarrow E_2} \tag{77}
\]
\[
\frac{B(\text{longstrid}_1) = (m_1, E_1) \quad \cdots \quad B(\text{longstrid}_n) = (m_n, E_n)}{B \vdash \text{open longstrid}_1 \cdots \text{ longstrid}_n \Rightarrow E_1 + \cdots + E_n} \tag{78}
\]
\[
\frac{B(\text{sigid}_1) \geq (m_1, E_1) \quad \cdots \quad B(\text{sigid}_n) \geq (m_n, E_n)}{B \vdash \text{include sigid}_1 \cdots \text{ sigid}_n \Rightarrow E_1 + \cdots + E_n} \tag{79}
\]
\[
\frac{B \vdash \Rightarrow \{\} \text{ in Env}}{B \vdash \text{spec} \Rightarrow E_1 \quad B + E_1 \vdash \text{spec}_2 \Rightarrow E_2}{B \vdash \text{spec} \{;\} \text{ spec}_2 \Rightarrow E_1 + E_2} \tag{81}
\]

Comments:

(70) $VE$ is determined by $B$ and $\text{valdesc}$.

(71)–(73) The type functions in $TE$ may be chosen to achieve the sharing hypothesis of rule 89 or the enrichment conditions of rules 62 and 99. In particular, the type names in $TE$ in rule 73 need not be new. Also, in rule 71 the type functions in $TE$ may admit equality.

(74) $EE$ is determined by $B$ and $\text{exdesc}$ and contains monotypes only.

(79) The names in the instances may be chosen to achieve sharing or enrichment conditions.

Value Descriptions

\[
\frac{C \vdash \text{ty } \Rightarrow \tau \quad \langle C \vdash \text{valdesc } \Rightarrow \text{VE} \rangle}{C \vdash \text{var : ty } \langle \text{and valdesc} \rangle \Rightarrow \{\text{var } \mapsto \tau\} \langle + \text{VE} \rangle} \tag{82}
\]

Type Descriptions

\[
\frac{\text{tyvarseq } = \alpha^{(k)}}{\langle C \vdash \text{typdesc } \Rightarrow \text{TE} \rangle \quad \text{arity } \theta = k}{\langle C \vdash \text{tyvarseq tycon } \langle \text{and typdesc} \rangle \Rightarrow \{\text{tycon } \mapsto (\theta, \{\})\} \langle + \text{TE} \rangle} \tag{83}
\]

Comment: Note that any $\theta$ of arity $k$ may be chosen but that the constructor environment in the resulting type structure must be empty. For example, $\text{datatype } s = c \text{ type } t \text{ sharing } s = t$ is a legal specification, but the type structure bound to $t$ does not bind any value constructors.
5.14 Inference Rules

Datatype Descriptions

\[ C \vdash \text{datdesc} \Rightarrow VE, TE \]

\[ tyvareq = \alpha^{(k)} \quad C, \alpha^{(k)}t \vdash \text{condesc} \Rightarrow CE \quad \langle C \vdash \text{datdesc} \Rightarrow VE, TE \rangle \]

\[ C \vdash tyvareq \quad tycon = \text{condesc} \quad \langle \text{and datdesc} \rangle \Rightarrow \]

\[ \text{ClosCE}(+VE), \ \{ tycon \mapsto (t, \text{ClosCE}) \} \quad (+TE) \]

(84)

Constructor Descriptions

\[ C, \tau \vdash \text{condesc} \Rightarrow CE \]

\[ \langle C \vdash ty \Rightarrow r' \rangle \quad \langle \{ C, \tau \vdash \text{condesc} \Rightarrow CE \} \rangle \]

\[ C, \tau \vdash \text{con} \langle \text{of } ty \rangle \langle \{ \text{or con desc} \} \rangle \Rightarrow \]

\[ \{ \text{con} \mapsto \tau \} \langle + \{ \text{con} \mapsto \tau' \mapsto \tau \} \rangle \langle (+ CE) \} \]

(85)

Exception Descriptions

\[ C \vdash \text{exdesc} \Rightarrow EE \]

\[ \langle C \vdash ty \Rightarrow r \quad tyvars(r) = \emptyset \rangle \quad \langle \{ C \vdash \text{exdesc} \Rightarrow EE \} \rangle \]

\[ C \vdash \text{excon} \langle \text{of } ty \rangle \langle \{ \text{and exdesc} \} \rangle \Rightarrow \]

\[ \{ \text{excon} \mapsto \text{exn} \} \langle + \{ \text{excon} \mapsto \tau \rightarrow \text{exn} \} \rangle \langle (+ EE) \} \]

(86)

Structure Descriptions

\[ B \vdash \text{strdesc} \Rightarrow SE \]

\[ B \vdash \text{sigexp} \Rightarrow S \quad \langle B \vdash \text{strdesc} \Rightarrow SE \rangle \]

\[ B \vdash \text{strid} : \text{sigexp} \langle \text{and strdesc} \rangle \Rightarrow \{ \text{strid} \mapsto S \} \langle (+ SE) \} \]

(87)

Sharing Equations

\[ B \vdash \text{share} \Rightarrow \{ \} \]

\[ m \text{ of } B(\text{longstrid}_1) = \cdots = m \text{ of } B(\text{longstrid}_n) \]

\[ B \vdash \text{longstrid}_1 = \cdots = \text{longstrid}_n \Rightarrow \{ \} \]

(88)

\[ \theta \text{ of } B(\text{longtycon}_1) = \cdots = \theta \text{ of } B(\text{longtycon}_n) \]

\[ B \vdash \text{type longtycon}_1 = \cdots = \text{longtycon}_n \Rightarrow \{ \} \]

(89)

\[ B \vdash \text{share}_1 \Rightarrow \{ \} \quad B \vdash \text{share}_2 \Rightarrow \{ \} \]

\[ B \vdash \text{share}_1 \text{ and share}_2 \Rightarrow \{ \} \]

(90)

Comments:

(88) By the definition of consistency the premise is weaker than

\[ B(\text{longstrid}_1) = \cdots = B(\text{longstrid}_n). \] Two different structures with the same

name may be thought of as representing different views. The requirement

that \( B \) is consistent forces different views to be consistent.
By the definition of consistency the premise is weaker than $B(\text{longtycon}_1) = \cdots = B(\text{longtycon}_n)$. A type structure with empty constructor environment may have the same type name as one with a non-empty constructor environment; the former could arise from a type description, and the latter from a datatype description. However, the requirement that $B$ is consistent will prevent two type structures with constructor environments which have different non-empty domains from sharing the same type name.

Functor Specifications

$$\begin{align*}
B \vdash \text{fundesc} \Rightarrow F \\
\frac{}{B \vdash \text{functor fundesc} \Rightarrow F}
\end{align*}$$ (91)

$$\begin{align*}
B \vdash \Rightarrow \emptyset
\end{align*}$$ (92)

$$\begin{align*}
B \vdash \text{funspec}_1 \Rightarrow F_1 \\
B + F_1 \vdash \text{funspec}_2 \Rightarrow F_2 \\
\frac{}{B \vdash \text{funspec}_1 (;) \text{funspec}_2 \Rightarrow F_1 + F_2}
\end{align*}$$ (93)

Comments:

(91) The second closure restriction of Section 3.6 can be enforced by replacing the $B$ in the premise by $B_0 + G$ of $B$.

Functor Descriptions

$$\begin{align*}
B \vdash \text{funsigexp} \Rightarrow \Phi \\
\frac{}{B \vdash \text{funid funsigexp (and fundesc)} \Rightarrow \{\text{funid} \mapsto \Phi\}(+ F)}
\end{align*}$$ (94)

Functor Signature Expressions

$$\begin{align*}
B \vdash \text{sigexp} \Rightarrow (N)S \\
B \oplus \{\text{strid} \mapsto S\} \vdash \text{sigexp'} \Rightarrow (N')S'
\frac{}{B \vdash (\text{strid : sigexp : sigexp'}) \Rightarrow (N)(S,(N')S')}
\end{align*}$$ (95)

Comment: The signatures $(N)S$ and $(N')S'$ are principal and type-explicit, see rule 65.

Functor Declarations

$$\begin{align*}
B \vdash \text{funbind} \Rightarrow F \\
\frac{}{B \vdash \text{functor funbind} \Rightarrow F}
\end{align*}$$ (96)

$$\begin{align*}
B \vdash \Rightarrow \emptyset
\end{align*}$$ (97)
\[ B \vdash \text{fundec}_1 \Rightarrow F_1 \quad B + F_1 \vdash \text{fundec}_2 \Rightarrow F_2 \]

\[ B \vdash \text{fundec}_1 \land \text{fundec}_2 \Rightarrow F_1 + F_2 \]  \hfill (98)

Comments:

(96) The third closure restriction of Section 3.6 can be enforced by replacing the symbol \( B \) in the premise by \( B_0 + (G \text{ of } B) + (F \text{ of } B) \).

Functor Bindings

\[ B \vdash \text{sigexp} \Rightarrow (N)S \quad B \uplus \{ \text{strid} \mapsto S \} \vdash \text{strexp} \Rightarrow S' \]

\[ \langle B \uplus \{ \text{strid} \mapsto S \} \vdash \text{sigexp} \Rightarrow \Sigma', \Sigma' \geq S'' \prec S' \rangle \]

\[ N' = \text{names } S' \setminus ((N \text{ of } B) \cup N) \]

\[ \langle \langle B \vdash \text{funbind} \Rightarrow F \rangle \rangle \]  \hfill (99)

Comment: The principality requirement on \((N)S\) implicit in the first premise forces \((N)S\) to be as general as possible given the sharing constraints in \text{sigexp}. The requirement that \((N)S\) be type-explicit ensures that there is at most one realisation via which an actual argument can match \((N)S\). Since \uplus is used, any structure name \( m \) and type name \( t \) in \( S \) acts like a constant in the functor body; in particular, it ensures that further names generated during elaboration of the body are distinct from \( m \) and \( t \). The set \( N' \) is chosen such that every name free in \((N)S\) or \((N)(S,(N')S')\) is free in \( B \).

Top-level Declarations

\[ B \vdash \text{strdec} \Rightarrow E \quad \text{imptyvars } E = \emptyset \]  \hfill (100)

\[ B \vdash \text{strdec} \Rightarrow (\text{names } E, E) \text{ in Basis} \]

\[ B \vdash \text{sigdec} \Rightarrow G \quad \text{imptyvars } G = \emptyset \]  \hfill (101)

\[ B \vdash \text{sigdec} \Rightarrow (\text{names } G, G) \text{ in Basis} \]

\[ B \vdash \text{fundec} \Rightarrow F \quad \text{imptyvars } F = \emptyset \]  \hfill (102)

\[ B \vdash \text{fundec} \Rightarrow (\text{names } F, F) \text{ in Basis} \]

Comments:

(100)–(102) The side conditions ensure that no free imperative type variables enter the basis.
5.15 Functor Signature Matching

As pointed out in Section 3.4 on the grammar for Modules, there is no phrase class whose elaboration requires matching one functor signature to another functor signature. But a precise definition of this matching is needed, since a functor \( g \) may only be separately compiled in the presence of specification of any functor \( f \) to which \( g \) refers, and then a real functor \( f \) must match this specification. In the case, then, that \( f \) has been specified by a functor signature

\[
\Phi_1 = (N_1)(S_1, (N'_1)S'_1)
\]

and that later \( f \) is declared with functor signature

\[
\Phi_2 = (N_2)(S_2, (N'_2)S'_2)
\]

the following matching rule will be employed:

A functor signature \( \Phi_2 = (N_2)(S_2, (N'_2)S'_2) \) matches another functor signature, \( \Phi_1 = (N_1)(S_1, (N'_1)S'_1) \), if there exists a realisation \( \varphi \) such that

1. \((N_1)S_1\) matches \((N_2)S_2\) via \( \varphi \), and
2. \(\varphi((N'_2)S'_2)\) matches \((N'_1)S'_1\).

The first condition ensures that the real functor signature \( \Phi_2 \) for \( f \) requires the argument \( strexp \) of any application \( f(strexp) \) to have no more sharing, and no more richness, than was predicted by the specified signature \( \Phi_1 \). The second condition ensures that the real functor signature \( \Phi_2 \), instantiated to \((\varphi S_2, \varphi ((N'_2)S'_2))\), provides in the result of the application \( f(strexp) \) no less sharing, and no less richness, than was predicted by the specified signature \( \Phi_1 \).
nature of exception bindings; each evaluation of a declaration of an exception constructor binds it to a new unique name.

6.3 Compound Objects

The compound objects for the dynamic semantics are shown in Figure 13. Many conventions and notations are adopted as in the static semantics; in particular projection, injection and modification all retain their meaning. We generally omit the injection functions taking Con, Con × Val etc into Val. For records \( r \in \text{Record} \) however, we write this injection explicitly as "in Val"; this accords with the fact that there is a separate phrase class ExpRow, whose members evaluate to records.

We take \( \cup \) to mean disjoint union over semantic object classes. We also understand all the defined object classes to be disjoint. A particular case deserves mention; ExVal and Pack (exception values and packets) are isomorphic classes, but the latter class corresponds to exceptions which have been raised, and therefore has different semantic significance from the former, which is just a subclass of values.

Although the same names, e.g. \( E \) for an environment, are used as in the static semantics, the objects denoted are different. This need cause no confusion since the static and dynamic semantics are presented separately. An important point is that structure names \( m \) have no significance at all in the dynamic semantics; this explains why the object class \( \text{Str} = \text{StrName} \times \text{Env} \) is absent here – for the dynamic semantics the concepts structure and environment coincide.
6.4 Basic Values

The basic values in BasVal are the values bound to predefined variables. These values are denoted by the identifiers to which they are bound in the initial dynamic basis (see Appendix D), and are as follows:

\[
\text{abs floor real sqrt sin cos arctan exp ln size chr ord explode implode div mod ^ / * + - = <> <= => std_in std_out open_in open_out close_in close_out input output lookahead end_of_stream}
\]

The meaning of basic values (almost all of which are functions) is represented by the function

\[
\text{APPLY : BasVal } \times \text{ Val } \rightarrow \text{ Val } \cup \text{ Pack}
\]

which is detailed in Appendix D.

6.5 Basic Exceptions

A subset BasExName \subset ExName of the exception names are bound to predefined exception constructors. These names are denoted by the identifiers to which they are bound in the initial dynamic basis (see Appendix D), and are as follows:

\[
\text{Abs Ord Chr Div Mod Quot Prod}
\]
\[
\text{Neg Sum Diff Floor Sqrt Exp Ln Io Match Bind Interrupt}
\]

The exceptions on the first two lines are raised by corresponding basic functions, where \(^/\) correspond respectively to Neg Quot Prod Sum Diff. The details are given in Appendix D. The exception \((\text{Io, s})\), where \(s\) is a string, is raised by certain of the basic input/output functions, as detailed in Appendix D. The exceptions Match and Bind are raised upon failure of pattern-matching in evaluating a function \(fn\) match or a \(valbind\), as detailed in the rules to follow. Finally, Interrupt is raised by external intervention.

Recall from Section 4.11 that in the context \(fn\) match, the match must be irredundant and exhaustive and that the compiler should flag the match if it violates these restrictions. The exception Match can only be raised for a match which is not exhaustive, and has therefore been flagged by the compiler.

For each value binding \(pat = exp\) the compiler must issue a report (but still compile) if either \(pat\) is not exhaustive or \(pat\) contains no variable. This will (on both counts) detect a mistaken declaration like \(\text{val nil} = exp\) in which the user expects to declare a new variable nil (whereas the language dictates that \(\text{nil}\) is here a constant pattern, so no variable gets declared). However, these warnings should not be given when the binding is a component of a top-level declaration \(\text{val valbind};\ e.g. val x::1 = exp_1\ and \ y = exp_2\) is not faulted by the compiler at top level, but may of course generate a \text{Bind} exception.
6.6 Closures

The informal understanding of a closure \((\text{match}, E, VE)\) is as follows: when the closure is applied to a value \(v\), \text{match} \ will be evaluated against \(v\), in the environment \(E\) modified in a special sense by \(VE\). The domain \(\text{Dom} \ VE\) of this third component contains those function identifiers to be treated recursively in the evaluation. To achieve this effect, the evaluation of \text{match} \ will take place not in \(E + VE\) but in \(E + \text{Rec} \ VE\), where

\[
\text{Rec} : \text{VarEnv} \rightarrow \text{VarEnv}
\]

is defined as follows:

- \(\text{Dom} (\text{Rec} \ VE) = \text{Dom} \ VE\)
- If \(VE(var) \notin \text{Closure}\), then \((\text{Rec} \ VE)(var) = VE(var)\)
- If \(VE(var) = (\text{match}', E', VE')\) then \((\text{Rec} \ VE)(var) = (\text{match}', E', VE')\)

The effect is that, before application of \((\text{match}, E, VE)\) to \(v\), the closure values in \(\text{Ran} \ VE\) are "unrolled" once, to prepare for their possible recursive application during the evaluation of \text{match} upon \(v\).

This device is adopted to ensure that all semantic objects are finite (by controlling the unrolling of recursion). The operator \text{Rec} \ is invoked in just two places in the semantic rules: in the rule for recursive value bindings of the form "\(\text{rec valbind}\)”, and in the rule for evaluating an application expression "\(exp \ atexp\)” in the case that \(exp\) evaluates to a closure.

6.7 Inference Rules

The semantic rules allow sentences of the form

\[
s, A \vdash \text{phrase} \Rightarrow A', s'
\]

to be inferred, where \(A\) is usually an environment, \(A'\) is some semantic object and \(s, s'\) are the states before and after the evaluation represented by the sentence. Some hypotheses in rules are not of this form; they are called side-conditions. The convention for options is the same as for the Core static semantics.

In most rules the states \(s\) and \(s'\) are omitted from sentences; they are only included for those rules which are directly concerned with the state – either referring to its contents or changing it. When omitted, the convention for restoring them is as follows. If the rule is presented in the form

\[
A_1 \vdash \text{phrase}_1 \Rightarrow A'_1 \quad A_2 \vdash \text{phrase}_2 \Rightarrow A'_2 \quad \cdots \\
\quad \cdots \quad A_n \vdash \text{phrase}_n \Rightarrow A'_n
\]

\[
A \vdash \text{phrase} \Rightarrow A'
\]
then the full form is intended to be

\[ s_0, A_1 \vdash \text{phrase}_1 \Rightarrow A'_1, s_1 \quad s_1, A_2 \vdash \text{phrase}_2 \Rightarrow A'_2, s_2 \quad \ldots \]
\[ \quad s_{n-1}, A_n \vdash \text{phrase}_n \Rightarrow A'_n, s_n \]
\[ s_0, A \vdash \text{phrase} \Rightarrow A', s_n \]

(Any side-conditions are left unaltered). Thus the left-to-right order of the hypotheses indicates the order of evaluation. Note that in the case \( n = 0 \), when there are no hypotheses (except possibly side-conditions), we have \( s_n = s_0 \); this implies that the rule causes no side effect. The convention is called the state convention, and must be applied to each version of a rule obtained by inclusion or omission of its options.

A second convention, the exception convention, is adopted to deal with the propagation of exception packets \( p \). For each rule whose full form (ignoring side-conditions) is

\[ s_1, A_1 \vdash \text{phrase}_1 \Rightarrow A'_1, s'_1 \quad \ldots \quad s_n, A_n \vdash \text{phrase}_n \Rightarrow A'_n, s'_n \]
\[ s, A \vdash \text{phrase} \Rightarrow A', s' \]

and for each \( k, 1 \leq k \leq n \), for which the result \( A'_k \) is not a packet \( p \), an extra rule is added of the form

\[ s_1, A_1 \vdash \text{phrase}_1 \Rightarrow A'_1, s'_1 \quad \ldots \quad s_k, A_k \vdash \text{phrase}_k \Rightarrow p', s' \]
\[ s, A \vdash \text{phrase} \Rightarrow p', s' \]

where \( p' \) does not occur in the original rule.\(^1\) This indicates that evaluation of phrases in the hypothesis terminates with the first whose result is a packet (other than one already treated in the rule), and this packet is the result of the phrase in the conclusion.

A third convention is that we allow compound variables (variables built from the variables in Figure 13 and the symbol \("/"
) to range over unions of semantic objects. For instance the compound variable \( v/p \) ranges over \( \text{Val} \cup \text{Pack} \). We also allow \( x/\text{FAIL} \) to range over \( X \cup \{\text{FAIL}\} \) where \( x \) ranges over \( X \); furthermore, we extend environment modification to allow for failure as follows:

\[ \text{VE} + \text{FAIL} = \text{FAIL}. \]

**Atomic Expressions**

\[ E \vdash \text{atexp} \Rightarrow v/p \] \hspace{1cm} (103)

\[ E \vdash \text{scon} \Rightarrow \text{val}(\text{scon}) \]

\[ E(\text{longvar}) = v \]
\[ E \vdash \text{longvar} \Rightarrow v \] \hspace{1cm} (104)

\(^1\)There is one exception to the exception convention; no extra rule is added for rule 119 which deals with handlers, since a handler is the only means by which propagation of an exception can be arrested.
\[
\begin{align*}
\text{longcon} &= \text{strid}_1, \ldots, \text{strid}_k, \text{con} \\
E \vdash \text{longcon} \Rightarrow \text{con} \\
E(\text{longezcon}) &= \text{en} \\
E \vdash \text{longezcon} \Rightarrow \text{en} \\
(E \vdash \text{ex prow} \Rightarrow r) &
\end{align*}
\]

\[
E \vdash \{ (\text{ex prow}) \} \Rightarrow \{ \} (+r) \text{ in Val}
\]

\[
E \vdash \text{dec} \Rightarrow E' \quad E + E' \vdash \text{exp} \Rightarrow v
\]

\[
E \vdash \text{let } \text{dec in } \text{exp end} \Rightarrow v
\]

\[
E \vdash \text{exp} \Rightarrow v
\]

\[
E \vdash (\text{exp}) \Rightarrow v
\]

Comments:

(105) Value constructors denote themselves.

(106) Exception constructors are looked up in the exception environment component of \(E\).

Expression Rows

\[
\begin{align*}
E \vdash \text{exp} &\Rightarrow v \\
E &\vdash \text{ex prow} \Rightarrow r
\end{align*}
\]

\[
E \vdash \text{lab} = \text{exp} (, \text{ex prow}) \Rightarrow \{ \text{lab} \mapsto v \}(+r)
\]

Comment: We may think of components as being evaluated from left to right, because of the state and exception conventions.

Expressions

\[
\begin{align*}
E \vdash \text{atexp} &\Rightarrow v \\
E &\vdash \text{atexp} \Rightarrow v
\end{align*}
\]

\[
E \vdash \text{exp} \Rightarrow \text{con} \quad \text{con} \neq \text{ref} \\
E \vdash \text{atexp} \Rightarrow v
\]

\[
E \vdash \text{exp} \Rightarrow \text{en} \\
E \vdash \text{atexp} \Rightarrow v
\]

\[
s, E \vdash \text{exp} \Rightarrow \text{ref}, s' \\
s', E \vdash \text{atexp} \Rightarrow v, s''
\]

\[
a \notin \text{Dom} (\text{mem of } s'') \\
\]

\[
s, E \vdash \text{exp} \Rightarrow a, s''\{a \mapsto v\}
\]

\[
s, E \vdash \text{exp} \Rightarrow \{1 \mapsto a, 2 \mapsto v\}, s''
\]

\[
s, E \vdash \text{exp} \Rightarrow \{\} \text{ in Val, } s''\{a \mapsto v\}
\]
6.7 Inference Rules

\[
\begin{align*}
E \vdash \text{exp} &\Rightarrow b & E \vdash \text{atexp} &\Rightarrow v & \text{APPLY}(b, v) = v' \\
E \vdash \text{exp \ atexp} &\Rightarrow v' \\
E \vdash \text{exp} &\Rightarrow (\text{match}, E', \text{VE}) & E \vdash \text{atexp} &\Rightarrow v \\
E' + \text{RecVE}, v \vdash \text{match} &\Rightarrow v' \\
E \vdash \text{exp \ atexp} &\Rightarrow v' \\
E \vdash \text{exp} &\Rightarrow (\text{match}, E', \text{VE}) & E \vdash \text{atexp} &\Rightarrow v \\
E' + \text{RecVE}, v \vdash \text{match} &\Rightarrow \text{FAIL} \\
E \vdash \text{exp \ atexp} &\Rightarrow [\text{Match}] \\
E \vdash \text{exp} &\Rightarrow v \\
E \vdash \text{exp \ handle \ match} &\Rightarrow v \\
E \vdash \text{exp} &\Rightarrow [e] & E, e \vdash \text{match} &\Rightarrow v \\
E \vdash \text{exp \ handle \ match} &\Rightarrow v \\
E \vdash \text{exp} &\Rightarrow [e] & E, e \vdash \text{match} &\Rightarrow \text{FAIL} \\
E \vdash \text{exp \ handle \ match} &\Rightarrow [e] \\
E \vdash \text{exp} &\Rightarrow e \\
E \vdash \text{raise \ exp} &\Rightarrow [e] \\
E \vdash \text{fn \ match} &\Rightarrow (\text{match}, E, \{\})
\end{align*}
\]

Comments:

(114) The side condition ensures that a new address is chosen. There are no rules concerning disposal of inaccessible addresses ("garbage collection").

(112)–(118) Note that none of the rules for function application has a premise in which the operator evaluates to a constructed value, a record or an address. This is because we are interested in the evaluation of well-typed programs only, and in such programs \text{exp} will always have a functional type, so \(v\) will be either a closure, a constructor, a basic value or :=.

(119) This is the only rule to which the exception convention does not apply. If the operator evaluates to a packet then rule 120 or rule 121 must be used.

(121) Packets that are not handled by the \text{match} propagate.

(123) The third component of the closure is empty because the match does not introduce new recursively defined values.
Matches

\[ \begin{align*}
E, v \vdash \text{match} & \Rightarrow v'/p/\text{FAIL} \\
E, v \vdash \text{mrule} \Rightarrow v' & \\
E, v \vdash \text{mrule} \ (\text{match}) & \Rightarrow v' \\
E, v \vdash \text{mrule} & \Rightarrow \text{FAIL} \\
E, v \vdash \text{mrule} & \Rightarrow \text{FAIL} \\
E, v \vdash \text{mrule} & \Rightarrow \text{FAIL} \\
E, v \vdash \text{mrule} & \Rightarrow v'/\text{FAIL} \\
E \vdash \text{mrule} \mid \text{match} & \Rightarrow v'/\text{FAIL} 
\end{align*} \]  

Comment: A value \( v \) occurs on the left of the turnstile, in evaluating a \textit{match}. We may think of a \textit{match} as being evaluated \textit{against} a value; similarly, we may think of a pattern as being evaluated \textit{against} a value. Alternative match rules are tried from left to right.

Match Rules

\[ \begin{align*}
E, v \vdash \text{pat} & \Rightarrow \text{VE} \\
E + \text{VE} \vdash \text{exp} & \Rightarrow v' \\
E, v \vdash \text{pat} & \Rightarrow \text{exp} \Rightarrow v' \\
E, v \vdash \text{pat} & \Rightarrow \text{FAIL} \\
E, v \vdash \text{pat} & \Rightarrow \text{exp} \Rightarrow \text{FAIL} 
\end{align*} \]  

Declarations

\[ \begin{align*}
E \vdash \text{dec} & \Rightarrow E'/p \\
E \vdash \text{valbind} & \Rightarrow \text{VE} \\
E \vdash \text{val} \ \text{valbind} & \Rightarrow \text{VE} \ \text{in Env} \\
E \vdash \text{exbind} & \Rightarrow \text{EE} \\
E \vdash \text{exception} \ \text{exbind} & \Rightarrow \text{EE} \ \text{in Env} \\
E \vdash \text{local} \ \text{dec} _1 \ \text{in} \ \text{dec} _2 \ \text{end} & \Rightarrow E_2 \\
E(\text{longstrid}_1) = E_1 \quad \ldots \quad E(\text{longstrid}_k) = E_k \\
E \vdash \text{open} \ \text{longstrid}_1 \ \ldots \ \text{longstrid}_n & \Rightarrow E_1 + \cdots + E_k \\
E \vdash & \Rightarrow \{\} \ \text{in Env} \\
E \vdash \text{dec} _1 & \Rightarrow E_1 \\
E + E_1 \vdash \text{dec} _2 & \Rightarrow E_2 \\
E \vdash \text{dec} _1 (;i) \ \text{dec} _2 & \Rightarrow E_1 + E_2 
\end{align*} \]
6.7 Inference Rules

Value Bindings

\[
\begin{align*}
E \vdash exp \Rightarrow v & \quad E, v \vdash pat \Rightarrow VE \quad \langle E \vdash valbind \Rightarrow VE' \rangle \\
E \vdash pat = exp \text{ (and valbind)} \Rightarrow VE \langle + VE' \rangle
\end{align*}
\]  
(135)

\[
E \vdash exp \Rightarrow v \quad E, v \vdash pat \Rightarrow FAIL
\]

\[
E \vdash valbind \Rightarrow VE
\]

\[
E \vdash \text{rec valbind} \Rightarrow \text{RecVE}
\]

(137)

Exception Bindings

\[
\begin{align*}
en \not\in \text{ens of } s & \quad s' = s + \{en\} \quad \langle s', E \vdash \text{exbind} \Rightarrow EE, s'' \rangle \\
E, s \vdash \text{excon (and exbind)} \Rightarrow \{\text{excon} \mapsto \text{en}\} \langle + EE \rangle, s'(')
\end{align*}
\]  
(138)

\[
E(\text{longexcon}) = en \quad \langle E \vdash \text{exbind} \Rightarrow EE \rangle
\]

\[
E \vdash \text{excon} = \text{longexcon (and exbind)} \Rightarrow \{\text{excon} \mapsto \text{en}\} \langle + EE \rangle
\]

(139)

Comments:

(138) The two side conditions ensure that a new exception name is generated and recorded as “used” in subsequent states.

Atomic Patterns

\[
E, v \vdash \text{atpat} \Rightarrow VE/FAIL
\]

\[
\begin{align*}
E, v \vdash \_ \Rightarrow \{\} \\
v = \text{val(scon)} \quad E, v \vdash \text{scon} \Rightarrow \{\} \\
v \neq \text{val(scon)} \quad E, v \vdash \text{scon} \Rightarrow \text{FAIL}
\end{align*}
\]  
(140)

(141)

(142)

(143)

\[
\begin{align*}
\text{longcon} = \text{strid}_1, \ldots, \text{strid}_k, \text{con} & \quad v = \text{con} \\
E, v \vdash \text{longcon} \Rightarrow \{\}
\end{align*}
\]  
(144)

\[
\begin{align*}
\text{longcon} = \text{strid}_1, \ldots, \text{strid}_k, \text{con} & \quad v \neq \text{con} \\
E, v \vdash \text{longcon} \Rightarrow \text{FAIL}
\end{align*}
\]  
(145)

\[
E(\text{longexcon}) = v
\]

\[
E, v \vdash \text{longexcon} \Rightarrow \{\}
\]

(146)
6 DYNAMIC SEMANTICS FOR THE CORE

\[
\frac{E(\text{longexcon}) \neq v}{E, v \vdash \text{longexcon} \Rightarrow \text{FAIL}} \quad (147)
\]

\[
v = \{ \} \text{(+r)} \text{ in Val} \quad \langle E, r \vdash \text{patrow} \Rightarrow \text{VE}/\text{FAIL} \rangle
\]

\[
E, v \vdash \{ \langle \text{patrow} \rangle \} \Rightarrow \{ \} \text{(+VE}/\text{FAIL} \}
\]

\[
E, v \vdash \text{pat} \Rightarrow \text{VE}/\text{FAIL}
\]

\[
E, v \vdash (\text{pat}) \Rightarrow \text{VE}/\text{FAIL}
\]

Comments:

(142),(145),(147) Any evaluation resulting in FAIL must do so because rule 142, rule 145, rule 147, rule 155, or rule 157 has been applied.

Pattern Rows

\[
\frac{E, r \vdash \ldots \Rightarrow \{ \} \quad (150)}{}
\]

\[
E, r(\text{lab}) \vdash \text{pat} \Rightarrow \text{FAIL}
\]

\[
E, r(\text{lab}) \vdash \text{lab} = \text{pat} (\text{, patrow}) \Rightarrow \text{FAIL}
\]

\[
E, r(\text{lab}) \vdash \text{pat} \Rightarrow \text{VE} \quad \langle E, r \vdash \text{patrow} \Rightarrow \text{VE'/FAIL} \rangle
\]

\[
E, r \vdash \text{lab} = \text{pat} (\text{, patrow}) \Rightarrow \text{VE(+ VE'/FAIL)}
\]

Comments:

(151),(152) For well-typed programs lab will be in the domain of r.

Patterns

\[
\frac{E, v \vdash \text{atpat} \Rightarrow \text{VE}/\text{FAIL}}{} \quad (153)
\]

\[
E, v \vdash \text{atpat} \Rightarrow \text{VE}/\text{FAIL}
\]

\[
\text{longcon} = \text{strid}_1, \ldots, \text{strid}_k, \text{con} \neq \text{ref} \quad v = (\text{con}, v')
\]

\[
E, v \vdash \text{atpat} \Rightarrow \text{VE}/\text{FAIL}
\]

\[
\text{longcon} = \text{strid}_1, \ldots, \text{strid}_k, \text{con} \neq \text{ref} \quad v \notin \{ \text{con} \} \times \text{Val}
\]

\[
E, v \vdash \text{longcon atpat} \Rightarrow \text{FAIL}
\]

\[
E(\text{longexcon}) = \text{en} \quad v = (\text{en}, v')
\]

\[
E, v \vdash \text{atpat} \Rightarrow \text{VE}/\text{FAIL}
\]

\[
E, v \vdash \text{longexcon atpat} \Rightarrow \text{VE}/\text{FAIL}
\]

\[
E(\text{longexcon}) = \text{en} \quad v \notin \{ \text{en} \} \times \text{Val}
\]

\[
E, v \vdash \text{longexcon atpat} \Rightarrow \text{FAIL}
\]
\[ s(a) = v \quad s, E, v \vdash \text{atpat} \Rightarrow VE/FAIL, s \]
\[ s, E, a \vdash \text{ref atpat} \Rightarrow VE/FAIL, s \]
\[ E, v \vdash \text{pat} \Rightarrow VE/FAIL \]
\[ E, v \vdash \text{var}(: ty) \text{ as pat} \Rightarrow \{\text{var} \mapsto v\} + VE/FAIL \]

Comments:

(155), (157) Any evaluation resulting in FAIL must do so because rule 142, rule 145, rule 147, rule 155, or rule 157 has been applied.
7 Dynamic Semantics for Modules

7.1 Reduced Syntax

Since signature expressions are mostly dealt with in the static semantics, the dynamic semantics need only take limited account of them. Unlike types, it cannot ignore them completely; the reason is that an explicit signature ascription plays the role of restricting the “view” of a structure - that is, restricting the domains of its component environments. However, the types and the sharing properties of structures and signatures are irrelevant to dynamic evaluation; the syntax is therefore reduced by the following transformations (in addition to those for the Core), for the purpose of the dynamic semantics of Modules:

- Qualifications “of ty” are omitted from exception descriptions.
- Any specification of the form “type typdesc”, “eqtype typdesc”, “datatype datdesc” or “sharing shareq” is replaced by the empty specification.
- The Modules phrase classes TypDesc, DatDesc, ConDesc and SharEq are omitted.

7.2 Compound Objects

The compound objects for the Modules dynamic semantics, extra to those for the Core dynamic semantics, are shown in Figure 14. An interface \( I \in \text{Int} \) represents

\[
\begin{align*}
(\text{strid} : I, \text{stexpr}(\cdot I\cdot), B) & \in \text{FunctorClosure} \\
& = (\text{StrId} \times \text{Int}) \times (\text{StrExp}(\times\text{Int})) \times \text{Basis} \\
(I\text{E}, \text{vars}, \text{excons}) \text{ or } I & \in \text{IntEnv} \times \text{Fin(Var)} \times \text{Fin(ExCon)} \\
I\text{E} & \in \text{IntEnv} = \text{StrId} \xrightarrow{\text{f}} \text{Int} \\
G & \in \text{SigEnv} = \text{SigId} \xrightarrow{\text{f}} \text{Int} \\
F & \in \text{FunEnv} = \text{FunId} \xrightarrow{\text{f}} \text{FunctorClosure} \\
(F, G, E) \text{ or } B & \in \text{Basis} = \text{FunEnv} \times \text{SigEnv} \times \text{Env} \\
(G, I\text{E}) \text{ or } I\text{B} & \in \text{IntBasis} = \text{SigEnv} \times \text{IntEnv}
\end{align*}
\]

Figure 14: Compound Semantic Objects

a “view” of a structure. Specifications and signature expressions will evaluate to interfaces; moreover, during the evaluation of a specification or signature expression, structures (to which a specification or signature expression may refer via “open”) are represented only by their interfaces. To extract an interface from a dynamic environment we define the operation

\[
\text{Inter} : \text{Env} \rightarrow \text{Int}
\]
as follows:

$$\text{Inter}(SE, VE, EE) = (IE, \text{Dom}VE, \text{Dom}EE)$$

where

$$IE = \{ \text{strid} \mapsto \text{Inter} E ; SE(\text{strid}) = E \}.$$ 

An interface basis $IB = (G, IE)$ is that part of a basis needed to evaluate signature expressions and specifications. The function Inter is extended to create an interface basis from a basis $B$ as follows:

$$\text{Inter}(F, G, E) = (G, IE \text{ of } (\text{Inter} E))$$

A further operation

$$\downarrow : \text{Env} \times \text{Int} \rightarrow \text{Env}$$

is required, to cut down an environment $E$ to a given interface $I$, representing the effect of an explicit signature ascription. It is defined as follows:

$$(SE, VE, EE) \downarrow (IE, \text{vars, excons}) = (SE', VE', EE')$$

where

$$SE' = \{ \text{strid} \mapsto E \downarrow I ; SE(\text{strid}) = E \text{ and } IE(\text{strid}) = I \}$$

and (taking $\downarrow$ now to mean restriction of a function domain)

$$VE' = VE \downarrow \text{vars, EE'} = EE \downarrow \text{excons}.$$ 

It is important to note that an interface is also a projection of the static value $\Sigma$ of a signature expression; it is obtained by omitting structure names $m$ and type environments $TE$, and replacing each variable environment $VE$ and each exception environment $EE$ by its domain. Thus in an implementation interfaces would naturally be obtained from the static elaboration; we choose to give separate rules here for obtaining them in the dynamic semantics since we wish to maintain our separation of the static and dynamic semantics, for reasons of presentation.

### 7.3 Inference Rules

The semantic rules allow sentences of the form

$$s, A \vdash \text{phrase} \Rightarrow A', s'$$

to be inferred, where $A$ is either a basis or an interface basis or empty, $A'$ is some semantic object and $s, s'$ are the states before and after the evaluation represented by the sentence. Some hypotheses in rules are not of this form; they are called side-conditions. The convention for options is the same as for the Core static semantics.

The state and exception conventions are adopted as in the Core dynamic semantics. However, it may be shown that the only Modules phrases whose evaluation may cause a side-effect or generate an exception packet are of the form $\text{strexp, strdec, strbind or topdec}$. 
Structure Expressions

\[
B \vdash \operatorname{strdec} \Rightarrow E \\
\frac{B \vdash \operatorname{struct} \operatorname{strdec} \text{ end} \Rightarrow E}{B \vdash \operatorname{strdec} \Rightarrow E}
\]

(160)

\[
B(\text{longstrid}) = E \\
\frac{B \vdash \text{longstrid} \Rightarrow E}{B \vdash \text{funid} (\operatorname{strexp}) \Rightarrow E'(\downarrow I')}
\]

(161)

\[
B \vdash \operatorname{strdec} \Rightarrow E \\
\frac{B' \vdash \operatorname{strexp} \Rightarrow E' \quad B' + \{\text{strid} \mapsto E \downarrow I\} \vdash \operatorname{strexp'} \Rightarrow E'}{B \vdash \text{let} \ \text{strdec in strexp} \ \text{end} \Rightarrow E'}
\]

(162)

(163)

Comments:

(162) Before the evaluation of the functor body \(\operatorname{strexp'}\), the actual argument \(E\) is cut down by the formal parameter interface \(I\), so that any opening of \(\text{strid}\) resulting from the evaluation of \(\operatorname{strexp'}\) will produce no more components than anticipated during the static elaboration.

Structure-level Declarations

\[
E \text{ of } B \vdash \operatorname{dec} \Rightarrow E' \\
\frac{B \vdash \operatorname{dec} \Rightarrow E'}{B \vdash \operatorname{dec} \Rightarrow E'}
\]

(164)

\[
B \vdash \operatorname{strbind} \Rightarrow SE \\
\frac{B \vdash \operatorname{structure} \operatorname{strbind} \Rightarrow SE \ \text{in Env}}{B \vdash \operatorname{structure} \operatorname{strbind} \Rightarrow SE \ \text{in Env}}
\]

(165)

\[
B \vdash \operatorname{strdec}_1 \Rightarrow E_1 \\
\frac{B + E_1 \vdash \operatorname{strdec}_2 \Rightarrow E_2}{B \vdash \text{local} \ \operatorname{strdec}_1 \ \text{in} \ \operatorname{strdec}_2 \ \text{end} \Rightarrow E_2}
\]

(166)

\[
B \vdash \Rightarrow \{\} \ \text{in Env}
\]

(167)

\[
B \vdash \operatorname{strdec}_1 \Rightarrow E_1 \\
\frac{B + E_1 \vdash \operatorname{strdec}_2 \Rightarrow E_2}{B \vdash \operatorname{strdec}_1 (;) \ \operatorname{strdec}_2 \Rightarrow E_1 + E_2}
\]

(168)
7.3 Inference Rules

Structure Bindings

\[ B \vdash \text{strbind} \Rightarrow \text{SE}/p \]

\[ B \vdash \text{strexp} \Rightarrow E \quad \langle \text{Inter } B \vdash \text{sigexp} \Rightarrow I \rangle \]
\[ \langle B \vdash \text{strbind} \Rightarrow \text{SE} \rangle \]
\[ B \vdash \text{strid} (\text{: sigexp}) = \text{strexp} \langle \langle \text{and strbind} \rangle \Rightarrow \{ \text{strid} \mapsto E(\downarrow I) \} \langle \downarrow \text{SE} \rangle \rangle \]

(169)

\[ \text{Comment: As in the static semantics, when present, sigexp constrains the "view" of the structure. The restriction must be done in the dynamic semantics to ensure that any dynamic opening of the structure produces no more components than anticipated during the static elaboration.} \]

Signature Expressions

\[ IB \vdash \text{spec} \Rightarrow I \]
\[ IB \vdash \text{sig spec end} \Rightarrow I \]

(170)

\[ IB(\text{sigid}) = I \]
\[ IB \vdash \text{sigid} \Rightarrow I \]

(171)

Signature Declarations

\[ IB \vdash \text{sigbind} \Rightarrow G \]
\[ IB \vdash \text{signature sigbind} \Rightarrow G \]

(172)

\[ IB \vdash \Rightarrow \{ \} \]
\[ IB \vdash \text{sigdec}_1 \Rightarrow G_1 \quad IB + G_1 \vdash \text{sigdec}_2 \Rightarrow G_2 \]
\[ IB \vdash \text{sigdec}_1 \langle ; \rangle \text{ sigdec}_2 \Rightarrow G_1 + G_2 \]

(174)

Signature Bindings

\[ IB \vdash \text{sigexp} \Rightarrow I \quad \langle IB \vdash \text{sigbind} \Rightarrow G \rangle \]
\[ IB \vdash \text{sigid = sigexp (and sigbind)} \Rightarrow \{ \text{sigid} \mapsto I \} \langle \downarrow G \rangle \]

(175)

Specifications

\[ \vdash \text{valdesc} \Rightarrow \text{vars} \]
\[ IB \vdash \text{val valdesc} \Rightarrow \text{vars in Int} \]

(176)

\[ \vdash \text{exdesc} \Rightarrow \text{excons} \]
\[ IB \vdash \text{exception exdesc} \Rightarrow \text{excons in Int} \]

(177)
\[ \frac{IB \vdash \text{strdesc} \Rightarrow IE}{IB \vdash \text{structure strdesc} \Rightarrow IE \text{ in Int}} \] (178)

\[ \frac{IB \vdash \text{spec}_1 \Rightarrow I_1 \quad IB + IE \text{ of } I_1 \vdash \text{spec}_2 \Rightarrow I_2}{IB \vdash \text{local spec}_1 \text{ in spec}_2 \text{ end} \Rightarrow I_2} \] (179)

\[ \frac{IB(\text{longstrid}_1) = I_1 \ldots \quad IB(\text{longstrid}_n) = I_n}{IB \vdash \text{open longstrid}_1 \ldots \text{longstrid}_n \Rightarrow I_1 + \ldots + I_n} \] (180)

\[ \frac{IB(\text{sigid}_1) = I_1 \ldots \quad IB(\text{sigid}_n) = I_n}{IB \vdash \text{include sigid}_1 \ldots \text{sigid}_n \Rightarrow I_1 + \ldots + I_n} \] (181)

\[ \frac{IB \vdash \text{in} \Rightarrow \{\} \text{ in Int}}{IB \vdash \text{spec}_1 \Rightarrow I_1 \quad IB + IE \text{ of } I_1 \vdash \text{spec}_2 \Rightarrow I_2}{IB \vdash \text{spec}_1 \langle ; \rangle \text{ spec}_2 \Rightarrow I_1 + I_2} \] (182)

Comments:

(179),(183) Note that \text{vars} of \text{I}_1 and \text{excons} of \text{I}_1 are not needed for the evaluation of \text{spec}_2.

Value Descriptions

\[ \frac{\vdash \text{valdesc} \Rightarrow \text{vars}}{\vdash \text{var (and valdesc)} \Rightarrow \{\text{var}\} \cup \text{vars}} \] (184)

Exception Descriptions

\[ \frac{\vdash \text{exdesc} \Rightarrow \text{excons}}{\vdash \text{excon (exdesc)} \Rightarrow \{\text{excon}\} \cup \text{excons}} \] (185)

Structure Descriptions

\[ IB \vdash \text{strdesc} \Rightarrow IE \]

\[ \frac{IB \vdash \text{sigexp} \Rightarrow I \quad (IB \vdash \text{strdesc} \Rightarrow IE)}{IB \vdash \text{strid : sigexp (and strdesc)} \Rightarrow \{\text{strid} \mapsto I\} \cup \text{IE}} \] (186)

Functor Bindings

\[ B \vdash \text{funbind} \Rightarrow F \]

\[ \frac{\text{Inter } B \vdash \text{sigexp} \Rightarrow I \quad (\text{Inter } B + \{\text{strid} \mapsto I\} \vdash \text{sigexp'} \Rightarrow I')}{\langle\langle B \vdash \text{funbind} \Rightarrow F\rangle\rangle} \]

\[ B \vdash \text{funid (strid : sigexp) \langle : sigexp'\rangle = \text{stexp (and funbind)} \Rightarrow \{\text{funid} \mapsto \text{strid : I, stexp': I'}, B\} \cup (+ F)\rangle} \] (187)
7.3 Inference Rules

Functor Declarations

\[ B \vdash \text{funbind} \Rightarrow F \]
\[ \frac{B \vdash \text{functor funbind} \Rightarrow F}{B \vdash \text{functor funbind} \Rightarrow F} \]  
(188)

\[ B \vdash \Rightarrow \{\} \]  
(189)

\[ B \vdash \text{fundec}_1 \Rightarrow F_1 \quad B + F_1 \vdash \text{fundec}_2 \Rightarrow F_2 \]
\[ \frac{B \vdash \text{fundec}_1 (;) \text{ fundec}_2 \Rightarrow F_1 + F_2}{B \vdash \text{fundec} \Rightarrow \text{Fundec}} \]  
(190)

Top-level Declarations

\[ B \vdash \text{topdec} \Rightarrow B'/p \]

\[ B \vdash \text{strdec} \Rightarrow E \]
\[ \frac{B \vdash \text{strdec} \Rightarrow E \text{ in Basis}}{B \vdash \text{strdec} \Rightarrow E \text{ in Basis}} \]  
(191)

\[ \text{Inter } B \vdash \text{sigdec} \Rightarrow G \]
\[ \frac{B \vdash \text{sigdec} \Rightarrow G \text{ in Basis}}{B \vdash \text{sigdec} \Rightarrow G \text{ in Basis}} \]  
(192)

\[ B \vdash \text{fundec} \Rightarrow F \]
\[ \frac{B \vdash \text{fundec} \Rightarrow F \text{ in Basis}}{B \vdash \text{fundec} \Rightarrow F \text{ in Basis}} \]  
(193)
8 Programs

The phrase class Program of programs is defined as follows

\[ \text{program} ::= \text{topdec} ; \langle \text{program} \rangle \]

Hitherto, the semantic rules have not exposed the interactive nature of the language. During an ML session the user can type in a phrase, more precisely a phrase of the form topdec as defined in Figure 8, page 14. Upon the following semicolon, the machine will then attempt to parse, elaborate and evaluate the phrase returning either a result or, if any of the phases fail, an error message. The outcome is significant for what the user subsequently types, so we need to answer question such as: if the elaboration of a top-level declaration succeeds, but its evaluation fails, then does the result of the elaboration get recorded in the static basis?

In practice, ML implementations may provide a directive as a form of top-level declaration for including programs from files rather than directly from the terminal. In case a file consists of a sequence of top-level declarations (separated by semicolons) and the machine detects an error in one of these, it is probably sensible to abort the execution of the directive. Rather than introducing a distinction between, say, batch programs and interactive programs, we shall tacitly regard all programs as interactive, and leave to implementors to clarify how the inclusion of files, if provided, affects the updating of the static and dynamic basis. Moreover, we shall focus on elaboration and evaluation and leave the handling of parse errors to implementors (since it naturally depends on the kind of parser being employed). Hence, in this section the execution of a program means the combined elaboration and evaluation of the program.

So far, for simplicity, we have used the same notation \( B \) to stand for both a static and a dynamic basis, and this has been possible because we have never needed to discuss static and dynamic semantics at the same time. In giving the semantics of programs, however, let us rename as StaticBasis the class Basis defined in the static semantics of modules, Section 5.1, and let us use \( B_{\text{STAT}} \) to range over StaticBasis. Similarly, let us rename as DynamicBasis the class Basis defined in the dynamic semantics of modules, Section 7.2, and let us use \( B_{\text{DYN}} \) to range over DynamicBasis. We now define

\[ B \text{ or } (B_{\text{STAT}}, B_{\text{DYN}}) \in \text{Basis} = \text{StaticBasis} \times \text{DynamicBasis}. \]

Further, we shall use \( \vdash_{\text{STAT}} \) for elaboration as defined in Section 5, and \( \vdash_{\text{DYN}} \) for evaluation as defined in Section 7. Then \( \vdash \) will be reserved for the execution of programs, which thus is expressed by a sentence of the form

\[ s, B \vdash \text{program} \Rightarrow B', s' \]

This may be read as follows: starting in basis \( B \) with state \( s \) the execution of \( \text{program} \) results in a basis \( B' \) and a state \( s' \).
It must be understood that executing a program never results in an exception. If the evaluation of a `topdec` yields an exception (for instance because of a `raise` expression or external intervention) then the result of executing the program "`topdec`" is the original basis together with the state which is in force when the exception is generated. In particular, the exception convention of Section 6.7 is not applicable to the ensuing rules.

We represent the non-elaboration of a top-level declaration by

... `\texttt{\textbf{\textbackslash s, B | \textbf{program} \Rightarrow B', s'}}`

(This covers also the case in which a user interrupts the elaboration.)

**Programs**

\[
\begin{align*}
B_{\text{STAT}} & \text{ of } B \vdash_{\text{STAT}} \text{topdec } \not\Rightarrow \quad \langle s, B \vdash \text{program} \Rightarrow B', s' \rangle \\
\text{\quad} & \quad \frac{\quad s, B \vdash \text{topdec} ; \langle \text{program} \rangle \Rightarrow B', s' \langle \rangle}{s, B \vdash \text{topdec} ; \langle \text{program} \rangle \Rightarrow B' \langle \rangle, s' \langle \rangle} \tag{194}
\end{align*}
\]

\[
\begin{align*}
B_{\text{STAT}} & \text{ of } B \vdash_{\text{STAT}} \text{topdec } \Rightarrow B_{\text{STAT}}^{(1)} \\
\text{\quad} & \quad \frac{s, B_{\text{DYN}} \text{ of } B \vdash_{\text{DYN}} \text{topdec } \Rightarrow p, s' \quad \langle s', B \vdash \text{program} \Rightarrow B', s'' \rangle}{s, B \vdash \text{topdec} ; \langle \text{program} \rangle \Rightarrow B' \langle \rangle, s'' \langle \rangle} \tag{195}
\end{align*}
\]

\[
\begin{align*}
B_{\text{STAT}} & \text{ of } B \vdash_{\text{STAT}} \text{topdec } \Rightarrow B_{\text{STAT}}^{(1)} \\
\text{\quad} & \quad \frac{s, B_{\text{DYN}} \text{ of } B \vdash_{\text{DYN}} \text{topdec } \Rightarrow B_{\text{DYN}}^{(1)}, s' \quad B' = B \oplus (B_{\text{STAT}}^{(1)}, B_{\text{DYN}}^{(1)})}{s, B \vdash \text{topdec} ; \langle \text{program} \rangle \Rightarrow B'' \langle \rangle, s'' \langle \rangle} \tag{196}
\end{align*}
\]

**Comments:**

(194) A failing elaboration has no effect whatever.

(195) An evaluation which yields an exception nullifies the change in the static basis, but does not nullify side-effects on the state which may have occurred before the exception was raised.

**Core language Programs**

A program is called a core language program if it can be parsed in the reduced grammar defined as follows:

1. Replace the definition of top-level declarations by

   \[
   \text{topdec ::= strdec}
   \]

2. Replace the definition of structure-level declarations by

   \[
   \text{strdec ::= dec}
   \]
3. Omit the open declaration from the syntax class of declarations \textit{dec}

4. Restrict the long identifier classes to identifiers, i.e. omit qualified identifiers.

This means that several components of a basis, for example the signature and functor environments, are irrelevant to the execution of a core language program.
A Appendix: Derived Forms

Several derived grammatical forms are provided in the Core; they are presented in Figures 15, 16 and 17. Each derived form is given with its equivalent form. Thus, each row of the tables should be considered as a rewriting rule

Derived form $\Rightarrow$ Equivalent form

and these rules may be applied repeatedly to a phrase until it is transformed into a phrase of the bare language. See Appendix B for the full Core grammar, including all the derived forms.

In the derived forms for tuples, in terms of records, we use $\overline{n}$ to mean the ML numeral which stands for the natural number $n$.

Note that a new phrase class `FvValBind` of function-value bindings is introduced, accompanied by a new declaration form `fun fvalbind`. The mixed forms `val rec fvalbind`, `val fvalbind` and `fun valbind` are not allowed – though the first form arises during translation into the bare language.

The following notes refer to Figure 17:

- There is a version of the derived form for function-value binding which allows the function identifier to be infixed; see Figure 20 in Appendix B.

- In the two forms involving `withtype`, the identifiers bound by `datbind` and by `typbind` must be distinct. Then the transformed binding `datbind'` in the equivalent form is obtained from `datbind` by expanding out all the definitions made by `typbind`. More precisely, if `typbind` is

$$tyvarseq_1 tycon_1 = ty_1 \text{ and } \ldots \text{ and } tyvarseq_n tycon_n = ty_n$$

then `datbind'` is the result of simultaneous replacement (in `datbind`) of every type expression `tyseq_i tycon_i` ($1 \leq i \leq n$) by the corresponding defining expression

$$ty_i\{tyseq_i/tyvarseq_i\}$$

Figure 18 shows derived forms for functors. They allow functors to take, say, a single type or value as a parameter, in cases where it would seem clumsy to "wrap up" the argument as a structure expression. These forms are currently more experimental than the bare syntax of modules, but we recommend implementors to include them so that they can be tested in practice. In the derived forms for functor bindings and functor signature expressions, `strid` is a new structure identifier and the form of `sigexp'` depends on the form of `sigexp` as follows. If `sigexp` is simply a signature identifier `sigid`, then `sigexp'` is also `sigid`; otherwise `sigexp` must take the form `sig spec_1 end`, and then `sigexp'` is `sig local open strid in spec_1 end end`.

Figure 18: Derived forms of Functors and Top-level Declarations
B Appendix: Full Grammar

The full grammar of programs is exactly as given at the start of Section 8.

The full grammar of Modules consists of the grammar of Figures 5–8 in Section 3, together with the derived forms of Figure 18 in Appendix A.

The remainder of this Appendix is devoted to the full grammar of the Core. Roughly, it consists of the grammar of Section 2 augmented by the derived forms of Appendix A. But there is a further difference: two additional subclasses of the phrase class Exp are introduced, namely AppExp (application expressions) and InfExp (infix expressions). The inclusion relation among the four classes is as follows:

\[
\text{AtExp} \subset \text{AppExp} \subset \text{InfExp} \subset \text{Exp}
\]

The effect is that certain phrases, such as "2 + while ...
... do ...", are now disallowed.

The grammatical rules are displayed in Figures 19, 20, 21 and 22. The grammatical conventions are exactly as in Section 2, namely:

- The brackets ( ) enclose optional phrases.
- For any syntax class X (over which \( x \) ranges) we define the syntax class Xseq (over which \( xseq \) ranges) as follows:
  \[
  xseq ::= x \quad \text{(singleton sequence)}
  
  (x_1, \ldots, x_n) \quad \text{(sequence,} \ n \geq 1)
  \]
  (Note that the "..." used here, a meta-symbol indicating syntactic repetition, must not be confused with "..." which is a reserved word of the language.)

- Alternative forms for each phrase class are in order of decreasing precedence. This precedence resolves ambiguity in parsing in the following way. Suppose that a phrase class — we take \( \text{exp} \) as an example — has two alternative forms \( F_1 \) and \( F_2 \), such that \( F_1 \) ends with an \( \text{exp} \) and \( F_2 \) starts with an \( \text{exp} \). A specific case is

\[
F_1: \ \text{if} \ \text{exp}_1 \ \text{then} \ \text{exp}_2 \ \text{else} \ \text{exp}_3
\]

\[
F_2: \ \text{exp} \ \text{handle} \ \text{match}
\]

It will be enough to see how ambiguity is resolved in this specific case.

Suppose that the lexical sequence

\[
\ldots \ldots \text{if} \ldots \text{then} \ldots \text{else} \ \text{exp} \ \text{handle} \ldots \ldots
\]

is to be parsed, where \text{exp} stands for a lexical sequence which is already determined as a subphrase (if necessary by applying the precedence rule).
Then the higher precedence of \( P_2 \) (in this case) dictates that \( \text{exp} \) associates to the right, i.e. that the correct parse takes the form

\[
\cdots \text{if} \cdots \text{then} \cdots \text{else (exp handle \( \cdots \))} \cdots
\]

not the form

\[
\cdots (\cdots \text{if} \cdots \text{then} \cdots \text{else exp}) \text{ handle} \cdots \cdots
\]

Note particularly that the use of precedence does not decrease the class of admissible phrases; it merely rejects alternative ways of parsing certain phrases. In particular, the purpose is not to prevent a phrase, which is an instance of a form with higher precedence, having a constituent which is an instance of a form with lower precedence. Thus for example

\[
\text{if} \cdots \text{then while} \cdots \text{do} \cdots \text{else while} \cdots \text{do} \cdots
\]

is quite admissible, and will be parsed as

\[
\text{if} \cdots \text{then (while} \cdots \text{do} \cdots) \text{ else (while} \cdots \text{do} \cdots)
\]

- \( L \) (resp. \( R \)) means left (resp. right) association.
- The syntax of types binds more tightly than that of expressions.
- Each iterated construct (e.g. \( \text{match}, \cdots \)) extends as far right as possible; thus, parentheses may be needed around an expression which terminates with a match, e.g. \( \text{"fn match"} \), if this occurs within a larger match.

\text{datbind} & ::= \langle \text{tyvarseq} \rangle \text{tycon} = \text{conbind} \langle \text{and datbind} \rangle \\
\text{conbind} & ::= \langle \text{op} \rangle \text{con} \langle \text{of ty} \rangle \langle \text{1 conbind} \rangle \\
\text{exbind} & ::= \langle \text{op} \rangle \text{excon} \langle \text{of ty} \rangle \langle \text{and exbind} \rangle \\
& \quad \langle \text{op} \rangle \text{excon} = \langle \text{op} \rangle \text{longexcon} \langle \text{and exbind} \rangle \\
\end{align*}
\]

Note: In the \textit{fvalbind} form, if \textit{var} has infix status then either \textit{op} must be present, or \textit{var} must be infixed. Thus, at the start of any clause, "\textit{op var (atpat, atpat')} \ldots" may be written "\textit{(atpat var atpat')} \ldots"; the parentheses may also be dropped if "\textit{: ty}" or "\textit{=}" follows immediately.

Figure 22: Grammar: Type expressions
C  Appendix: The Initial Static Basis

We shall indicate components of the initial basis by the subscript 0. The initial static basis is

\[ B_0 = (M_0, T_0), F_0, G_0, E_0 \]

where

- \( M_0 = \emptyset \)
- \( T_0 = \{ \text{bool}, \text{int}, \text{real}, \text{string}, \text{list}, \text{ref}, \text{exn}, \text{instream}, \text{outstream} \} \)
- \( F_0 = \{ \} \)
- \( G_0 = \{ \} \)
- \( E_0 = (SE_0, TE_0, VE_0, EE_0) \)

The members of \( T_0 \) are type names, not type constructors; for convenience we have used type-constructor identifiers to stand also for the type names which are bound to them in the initial static type environment \( TE_0 \). Of these type names, \text{list} and \text{ref} have arity 1, the rest have arity 0; all except \text{exn}, \text{instream} and \text{outstream} admit equality.

The components of \( E_0 \) are as follows:

- \( SE_0 = \{ \} \)
- \( VE_0 \) is shown in Figures 23 and 24. Note that \( \text{Dom } VE_0 \) contains those identifiers (\text{true}, \text{false}, \text{nil}, ::) which are basic value constructors, for reasons discussed in Section 4.3. \( VE_0 \) also includes \( EE_0 \), for the same reasons.
- \( TE_0 \) is shown in Figure 25. Note that the type structures in \( TE_0 \) contain the type schemes of all basic value constructors.
- \( \text{Dom } EE_0 = \text{BasExName} \), the set of basic exception names listed in Section 6.5. In each case the associated type is \text{exn} , except that \( EE_0(\text{Io}) = \text{string} \rightarrow \text{exn} \).

</tr>
</tbody>
</table>

Notes:

- In type schemes we have taken the liberty of writing \( ty_1 \ast ty_2 \) in place of \( \{1 \mapsto ty_1, 2 \mapsto ty_2 \} \).

- An identifier with type involving \text{num} stands for two functions – one in which \text{num} is replaced by \text{int} in its type, and another in which \text{num} is replaced by \text{real} in its type. Sometimes an explicit type constraint will be needed if the surrounding text does not determine the type of a particular occurrence of + (for example). For this purpose, the surrounding text is no larger than the enclosing top-level declaration; an implementation may require that a smaller context determines the type.

Figure 25: Static $\text{TE}_0$
Appendix: The Initial Dynamic Basis

We shall indicate components of the initial basis by the subscript 0. The initial dynamic basis is

\[ B_0 = F_0, G_0, E_0 \]

where

- \( F_0 = \{ \} \)
- \( G_0 = \{ \} \)
- \( E_0 = E'_0 + E''_0 \)

\( E'_0 \) contains bindings of identifiers to the basic values BasVal and basic exception names BasExName; in fact \( E'_0 = SE'_0, VE'_0, EE'_0 \), where:

- \( SE'_0 = \{ \} \)
- \( VE'_0 = \{ id \mapsto id ; id \in \text{BasVal} \} \cup \{ := \mapsto := \} \)
- \( EE'_0 = \{ id \mapsto id ; id \in \text{BasExName} \} \)

Note that \( VE'_0 \) is the identity function on BasVal; this is because we have chosen to denote these values by the names of variables to which they are initially bound. The semantics of these basic values (most of which are functions) lies principally in their behaviour under APPLY, which we describe below. On the other hand the semantics of := is provided by a special semantic rule, rule 115. Similarly, \( EE'_0 \) is the identity function on BasExName, the set of basic exception names, because we have also chosen these names to be just those exception constructors to which they are initially bound. These exceptions are raised by APPLY as described below.

\( E''_0 \) contains initial variable bindings which, unlike BasVal, are definable in ML; it is the result of evaluating the following declaration in the basis \( F_0, G_0, E'_0 \). For convenience, we have also included all basic infix directives in this declaration.

```
infix 3 o
infix 4  = <> < > <= >=
infix 5 @
infixr 5 ::
infix 6 + - ^
infix 7  div mod /*
```

```
fun (F o G)x = F(G x)

fun nil @ M = M
  | (x::L) @ M = x::(L @ M)
```
fun s ~ s' = implode((explode s) @ (explode s'))

fun map F nil = nil
   | map F (x::L) = (F x)::(map F L)

fun rev nil = nil
   | rev (x::L) = (rev L) @ [x]

fun not true = false
   | not false = true

fun ! (ref x) = x

We now describe the effect of APPLY upon each value \( b \in \text{BasVal} \). For special values, we shall normally use \( i, r, n, s \) to range over integers, reals, numbers (integer or real), strings respectively. We also take the liberty of abbreviating "APPLY(abs, r)" to "abs(r)", "APPLY(mod, \{1 \mapsto i, 2 \mapsto d\})" to "\( i \mod d \)", etc.

- \(~(n)\) returns the negation of \( n \), or the packet \([\text{Neg}]\) if the result is out of range.
- \( \text{abs}(n) \) returns the absolute value of \( n \), or the packet \([\text{Abs}]\) if the result is out of range.
- \( \text{floor}(r) \) returns the largest integer \( i \) not greater than \( r \); it returns the packet \([\text{Floor}]\) if \( i \) is out of range.
- \( \text{real}(i) \) returns the real value equal to \( i \).
- \( \text{sqrt}(r) \) returns the square root of \( r \), or the packet \([\text{Sqrt}]\) if \( r \) is negative.
- \( \sin(r) \), \( \cos(r) \) return the result of the appropriate trigonometric functions.
- \( \text{arctan}(r) \) returns the result of the appropriate trigonometric function in the range \( \pm \pi/2 \).
- \( \exp(r) \), \( \ln(r) \) return respectively the exponential and the natural logarithm of \( r \), or an exception packet \([\text{Exp}]\) or \([\text{Ln}]\) if the result is out of range.
- \( \text{size}(s) \) returns the number of characters in \( s \).
- \( \text{chr}(i) \) returns the character numbered \( i \) (see Section 2.2) if \( i \) is in the interval \([0, 255]\), and the packet \([\text{Chr}]\) otherwise.
• \textit{ord}(s) \text{ returns the number of the first character in } s \text{ (an integer in the interval } [0, 255], \text{ see Section 2.2), or the packet } [\text{Ord}] \text{ if } s \text{ is empty.}

• \textit{explode}(s) \text{ returns the list of characters (as single-character strings) of which } s \text{ consists.}

• \textit{implode}(d) \text{ returns the string formed by concatenating all members of the list } d \text{ of strings.}

• The arithmetic functions \textit{/, *, +, -} \text{ all return the results of the usual arithmetic operations, or exception packets respectively } [\text{Quot}], [\text{Prod}], [\text{Sum}], [\text{Diff}] \text{ if the result is undefined or out of range.}

• \textit{i \% d}, \textit{i \div d} \text{ return integers } r, q \text{ (remainder, quotient) determined by the equation } d \times q + r = i \text{, where either } 0 \leq r < d \text{ or } d < r \leq 0 \text{. Thus the remainder has the same sign as the divisor } d \text{. The packet } [\text{Mod}] \text{ or } [\text{Div}] \text{ is returned if } d = 0.

• The order relations \textit{<, >, <=, >=} \text{ return boolean values in accord with their usual meanings.}

• \textit{v_1 = v_2} \text{ returns } \text{true or false according as the values } v_1 \text{ and } v_2 \text{ are, or are not, identical. The type discipline (in particular, the fact that function types do not admit equality) ensures that equality is only ever applied to special values, nullary constructors, addresses, and values built out of such by record formation and constructor application.}

• \textit{v_1 \neq v_2} \text{ returns the opposite boolean value to } v_1 = v_2.

It remains to define the effect of APPLY upon basic values concerned with input/output; we therefore proceed to describe the ML input/output system.

Input/Output in ML uses the concept of a stream. A stream is a finite or infinite sequence of characters; if finite, it may or may not be terminated. (It may be convenient to think of a special end-of-stream character signifying termination, provided one realises that this "character" is never treated as data). Input streams – or \textit{instreams} – are of type \textit{instream} and will be denoted by \textit{is}; output streams – or \textit{outstreams} – are of type \textit{outstream} and will be denoted by \textit{os}. Both these types of stream are abstract, in the sense that streams may only be manipulated by the functions provided in BasVal.

Associated with an instream is a \textit{producer}, normally an I/O device or file; similarly an outstream is associated with a \textit{consumer}. After this association has been established – either initially or by the \textit{open_in} or \textit{open_out} function – the stream acts as a vehicle for character transmission from producer to program, or from program to consumer. The association can be broken by the \textit{close_in} or \textit{close_out} function. A closed stream permits no further character transmission; a closed instream is equivalent to one which is empty and terminated.
There are two streams in BasVal:

- **std.in**: an instream whose producer is the terminal.
- **std.out**: an outstream whose consumer is the terminal.

The other basic values concerned with Input/Output are all functional, and the effect of APPLY upon each of them given below. We take the liberty of abbreviating "APPLY(open_in, s)" to "open_in(s)" etc., and we shall use s and n to range over strings and integers respectively.

- **open_in(s)** returns a new instream **is**, whose producer is the external file named **s**. It returns exception packet

  ```
  [ (Io,"Cannot open s") ]
  ```

  if file **s** does not exist or does not provide read access.

- **open_out(s)** returns a new outstream **os**, whose consumer is the external file named **s**. If file **s** is non-existent, it is taken to be initially empty.

- **input(is, n)** returns a string **s** containing the first **n** characters of **is**, also removing them from **is**. If only **k < n** characters are available on **is**, then
  
  - If **is** is terminated after these **k** characters, the returned string **s** contains them alone, and they are removed from **is**.
  
  - Otherwise no result is returned until the producer of **is** either supplies **n** characters or terminates the stream.

- **lookahead(is)** returns a single-character string **s** containing the next character of **is**, without removing it. If no character is available on **is** then
  
  - If **is** is closed, the empty string is returned.
  
  - Otherwise no result is returned until the producer of **is** either supplies a character or closes the stream.

- **close_in(is)** empties and terminates the instream **is**.

- **end_of_stream(is)** returns **true** if **lookahead(is)** returns the empty string, **false** otherwise; it detects the end of the instream **is**.

- **output(os, s)** writes the characters of **s** to the outstream **os**, unless **os** is closed, in which case it returns the exception packet

  ```
  [ (Io,"Output stream is closed") ]
  ```

- **close_out(os)** terminates the outstream **os**.
Appendix: The Development of ML

This Appendix records the main stages in the development of ML, and the people principally involved. The main emphasis is upon the design of the language; there is also a section devoted to implementation. On the other hand, no attempt is made to record work on implementation environments, or on applications of the language.

Origins

ML and its semantic description have evolved over a period of about fourteen years. It is a fusion of many ideas from many people; in this appendix we try to record and to acknowledge the important precursors of its ideas, the important influences upon it, and the important contributions to its design, implementation and semantic description.

ML, which stands for meta language, was conceived as a medium for finding and performing proofs in a formal logical system. This application was the focus of the initial design effort, by Robin Milner in collaboration first with Malcolm Newey and Lockwood Morris, then with Michael Gordon and Christopher Wadsworth [11]. The intended application to proof affected the design considerably. Higher order functions in full generality seemed necessary for programming proof tactics and strategies, and also a robust type system (see below). At the same time, imperative features were important for practical reasons; no-one had experience of large useful programs written in a pure functional style. In particular, an exception-raising mechanism was highly desirable for the natural presentation of tactics.

The full definition of this first version of ML was included in a book [12] which describes LCF, the proof system which ML was designed to support. The details of how the proof application exerted an influence on design is reported by Milner [22]. Other early influences were the applicative languages already in use in Artificial Intelligence, principally LISP [19], ISWIM [17] and POP2 [5].

Polymorphic types

The polymorphic type discipline and the associated type-assignment algorithm were prompted by the need for security; it is vital to know that when a program produces an object which it claims to be a theorem, then it is indeed a theorem. A type discipline provides the security, but a polymorphic discipline also permits considerable flexibility.

The key ideas of the type discipline were evolved in combinatory logic by Haskell Curry and Roger Hindley, who arrived at different but equivalent algorithms for computing principal type schemes. Curry's [7] algorithm was by equation-solving; Hindley [14] used the unification algorithm of Alan Robinson
[27] and also presented the precursor of our type inference system. James Morris [24] independently gave an equation-solving algorithm very similar to Curry's. The idea of an algorithm for finding principal type schemes is very natural and may well have been known earlier. I am grateful to Roger Hindley for pointing out that Carew Meredith's inference rule for propositional logic called Condensed Detachment, defined in the early 1950s, clearly suggests that he knew such an algorithm [20].

Milner [21], during the design of ML, rediscovered principal types and their calculation by unification, for a language (slightly richer than combinatory logic) containing local declarations. He and Damas [9] presented the ML type inference systems following Hindley's style. Damas [8], using ideas from Michael Gordon, also devised the first mathematical treatment of polymorphism in the presence of references and assignment; recently Tofte [29] has produced a treatment which differs in some respects, but is easier to follow and has a simpler semantic presentation.

Refinement of the Core Language

Two movements led to the re-design of ML. One was the work of Rod Burstall and his group on specifications, crystallised in the specification language CLEAR [4] and in the functional programming language HOPE [3]; the latter was for expressing executable specifications. The outcome of this work which is relevant here was twofold. First, there were elegant programming features in HOPE, particularly pattern matching and clausal function definitions; second, there were ideas on modular construction of specifications, using signatures in the interfaces. A smaller but significant movement was by Luca Cardelli, who extended the data-type repertoire in ML by adding named records and variant types.

In 1983, Milner (prompted by Bernard Sufrin) wrote the first draft of a standard form of ML attempting to unite these ideas; over the next three years it evolved into the Standard ML Core Language. Notable here was the harmony found among polymorphism, HOPE patterns and Cardelli records, and the nice generalisations of ML exceptions due to ideas from Alan Mycroft, Brian Monahan and Don Sannella. A simple stream-based I/O mechanism was developed from ideas of Cardelli by Milner and Harper. The Standard ML Core Language is described in detail in a composite report [15] which also contains a description of the I/O mechanism and MacQueen's proposal for program modules (see later for discussion of this). Since then only few changes to the Core Language have occurred. Milner proposed equality types, and these were added, together with a few minor adjustments [23]. The latest and final development has been in the exception mechanism, by MacQueen using an idea from Burstall [1]; it unites the ideas of exception and data type construction.
Modules

Besides contributory ideas to the Core Language, HOPE [3] contained a simple notion of program module. The most important and original feature of ML Modules, however, stems from the work on parameterised specifications in CLEAR [4]. MacQueen, who was a member of Burstall's group at the time, designed [18] a new parametric module feature for HOPE inspired by the CLEAR work. He later extended the parameterisation ideas by a novel method of specifying sharing of components among the structure parameters of a functor, and produced a draft design which accommodated features already present in ML – in particular the polymorphic type system. This design was discussed in detail at Edinburgh, leading to MacQueen's first report on Modules [15].

Thereafter, the design came under close scrutiny through a draft operational static semantics and prototype implementation of it by Harper, through Kevin Mitchell's implementation of the evaluation, through a denotational semantics written by Don Sannella, and then through further work on operational semantics by Milner and Tofte. (More is said about this in the later section on Semantics.) In all of this work the central ideas withstood scrutiny, while it also became clear that there were gaps in the design and ambiguities in interpretation. (An example of a gap was the inability to specify sharing between a functor argument structure and its result structure; an example of an ambiguity was the question of whether sharing exists in a structure over and above what is specified in the signature expression which accompanies its declaration.)

Much discussion ensued; it was possible for a wider group to comment on Modules through using Harper's prototype implementation, while Harper, Milner and Tofte gained understanding during development of this semantics. In parallel, Sannella and Tarlecki explored the implications of Modules for the methodology of program development [28]. Tofte, in his thesis [29], proved several technical properties of Modules in a skeletal language, which generated considerable confidence in this design. A key point in this development was the proof of the existence of principal signatures, and, in the careful distinction between the notion of enrichment of structures, which allows more polymorphism and more components, and realisation which allows more sharing.

At a meeting in Edinburgh in 1987 a choice of two designs was presented, hinging upon whether or not a functor application should coerce its actual argument to its argument signature. The meeting chose coercion, and thereafter the production of Section 5 of this report – the Static Semantics of Modules – was a matter of detailed care. That section is undoubtedly the most original and demanding part of this semantics, just as the ideas of MacQueen upon which it is based are the most far-reaching extension to the original design of ML.
Implementation

The first implementation of ML was by Malcolm Newey, Lockwood Morris and Robin Milner in 1974, for the DEC10. Later Mike Gordon and Chris Wadsworth joined; their work was mainly in specialising ML towards machine-assisted reasoning. Around 1980 Luca Cardelli implemented a version on VAX; his work was later extended by Alan Mycroft, Kevin Mitchell and John Scott. This version contained one or two new data-type features, and was based upon the Functional Abstract Machine (FAM), a virtual machine which has been a considerable stimulus to later implementation. By providing a reasonably efficient implementation, this work enabled the language to be taught to students; this, in turn, prompted the idea that it could become a useful general purpose language.

In Gothenburg, an implementation was developed by Lennart Augustsson and Thomas Johnsson in 1982, using lazy evaluation rather than call-by-value; the result was called Lazy ML and is reported in [2]. This work is part of continuing research in many places on implementation of lazy evaluation in pure functional languages. But for ML, which includes exceptions and assignment, the emphasis has been mainly upon strict evaluation (call-by-value).

In Cambridge, in the early 1980s, Larry Paulson made considerable improvements to the Edinburgh ML compiler, as part of his wider programme of improving Edinburgh LCF to become Cambridge LCF [25]. This system has supported larger proofs than the Edinburgh system, and with greater convenience; in particular, the compiled ML code ran four to five times faster.

Around the same time Gérard Huet at INRIA (Versailles) adapted ML to Maclisp on Multics, again for use in machine-assisted proof. There was close collaboration between INRIA and Cambridge in this period. ML has undergone a separate development in the group at INRIA, arriving at a language and implementation known as CAML [6]; this is close to the core language of Standard ML, but does not include the Modules.

The first implementation of the Standard ML core language was by Mitchell, Mycroft and John Scott of Edinburgh, around 1984, and this was shortly followed by an implementation by David Matthews at Cambridge, carried out in his language Poly.

The prototype implementation of Modules, before that part of the language settled down, was done in 1985-6; Mitchell dealt with evaluation, while Harper tackled the elaboration (or ‘signature checking’) which raised problems of a kind not previously encountered. The Edinburgh implementation continues to play the role of a test-bed for language development.

Meanwhile Matthews’ Cambridge implementation also advanced to embrace Modules, and now adheres to the Standard. This implementation has supported applications of considerable size, both for machine-assisted proof and for hardware design. It is now available commercially from Imperial Software Technology.

In 1986, as the Modules definition was settling down, David MacQueen began
an implementation at Bell AT&T Laboratories, assisted by Andrew Appel, based upon the Edinburgh work. They were shortly joined by Trevor Jim. At the time of writing (May 1988) the first release of this implementation is completed, and adheres to the Standard. Work continues to improve its performance.

The Bell and Cambridge implementations, the former led by MacQueen and Appel, the latter by Matthews, are currently the most complete and highly engineered. Other currently active implementations are by Michael Hedlund at the Rutherford-Appleton Laboratory, by Robert Duncan, Simon Nichols and Aaron Sloman at the University of Sussex (POPLOG) and by Malcolm Newey and his group at the Australian National University.

Semantics

The description of the first version of ML [12] was informal, and in an operational style; around the same time a denotational semantics was written, but never published, by Mike Gordon and Robin Milner. Meanwhile structured operational semantics, presented as an inference system, was gaining credence as a tractable medium. This originates with the reduction rules of $\lambda$-calculus, but was developed more widely through the work of Plotkin [26], and also by Milner. This was at first only used for dynamic semantics, but later the benefit of using inference systems for both static and dynamic semantics became apparent. This advantage was realised when Gilles Kahn and his group at INRIA were able to execute early versions of both forms of semantics for the ML Core Language using their Typol system [10]. The static and dynamic semantics of the Core reached a final form mostly through work by Mads Tofte and Robin Milner.

The modules of ML presented little difficulty as far as dynamic semantics is concerned, but the static semantics of Modules was a concerted effort by several people. MacQueen's original informal description [15] was the starting point; Sannella wrote a denotational semantics for several versions, which showed that several issues had not been settled by the informal description. Robert Harper, while writing the first implementation of Modules, made the first draft of the static semantics. Harper's version made clear the importance of structure names; work by Milner and Tofte introduced further ideas including realisation; thereafter a concerted effort by all three led to several suggestions for modification of the language, and a small range of alternative interpretations; these were assessed in discussion with MacQueen, and more widely with the principal users of the language, and an agreed form was reached.

There is no doubt that the interaction between design and semantic description of Modules has been one of the most striking phases in the entire language development, leading (in the opinion of those involved) to a high degree of confidence both in the language and in the semantic method.
Literature

The present document is the definition of Standard ML; further versions of it will be produced as the language develops (but the intention is to minimise the number of versions). An informal definition, consistent with Version 2 of this document as far as the Core Language is concerned, is provided by [15], as modified by [23] and [1]. An elementary textbook covering the Core language has been recently published, written by Åke Wikström [30]. Robert Harper [13] has written a shorter introduction which also includes material on Modules.

Further acknowledgments

Apart from the people mentioned above we also acknowledge the following, all of whom have contributed in some way to the evolution of ML: Guy Cousineau, Jim Hook, Gerard Huet, Gilles Kahn, Brian Monahan, Peter Mosses, Alan Mycroft, David Park, David Rydeheard, David Schmidt, Stefan Sokolowski, Bernard Sufrin, Philip Wadler.

type name (τ), 16, 19, 21, 22, 25, 27, 30–34, 41, 75
type name set, 17, 31
type realisation (ϕTy), 33
type scheme (σ), 17, 19–21, 23, 28, 34, 41, 74, 75
type specification, 13, 39, 56
type structure (θ, CE), 17, 21, 22, 25, 27, 29, 32, 34, 39–42, 74, 75
type variable (tyvar, α), 4, 9, 16
in type expression, 9, 29, 72
equality, 4, 16, 18, 19
imperative, 4, 16, 17, 19, 21, 25, 27, 28, 30, 43
applicative, 4, 16, 17, 19, 21, 25, 27, 28
explicit, 19, 20, 25, 26
type vector (τ(h)), 17–19
TypeFcn (type functions), 17
TypeScheme (type schemes), 17
tyrow (type-expression row), 7, 9, 30, 45, 72
TyRow (type-expression rows), 7, 9, 45
TyStr (type structures), 17
tyvar (see type variable)
TyVar (type variables), 4, 16
tyvars (free type variables), 17
tyvarseq (type variable sequence), 7
TyVarSet, 17

U

U (explicit type variables), 17, 18, 20, 25, 26
unit, 75
unguarded type variable, 20

V

v (value), 46, 49–52
val (function on special constants), 45, 49, 53
Val (values), 46
val, 3, 8, 13, 25, 39, 52, 59, 71
valbind (value binding), 7, 8, 20, 21, 25, 26, 53, 71
   simple, 8, 26, 53, 71
   recursive, 8, 26, 27, 53, 71
Valbind (value bindings), 7
valdesc (value description), 11, 13, 40, 60
ValDesc (value descriptions), 11
value binding (valbind), 7, 8, 20, 21, 25, 26, 53, 71
   simple, 8, 26, 53, 71
   recursive, 8, 26, 27, 53, 71
value constant (con)
   in pattern, 9, 28, 53, 72
value constructor (con), 4
   as atomic expression, 8, 23, 50, 70
   scope, 5, 18
value construction
   in pattern, 9, 29, 54, 72
   infixed, in pattern, 9, 72
value declaration, 8, 20, 25, 52, 71
value description (valdesc), 11, 13, 40, 60
value variable (var), 4
   as atomic expression, 8, 23, 49, 70
   in pattern, 9, 28, 53, 72
value specification, 13, 39, 59
var (see value variable)
Var (value variables), 4
VarEnv (variable environments), 17, 46
variable (see value variable)
variable environment (VE)
   static, 17, 18, 20, 21, 25–29, 34, 40, 41, 57, 74, 75
dynamic, 46, 48, 53, 54, 57, 76
vars (set of value variables), 56, 60
VE (see variable environment)
via φ, 35, 44
view of a structure, 38, 41, 56, 58, 59

W

well-formed
   type environment, 21
   signature, 32
   functor signature, 32
   assembly, 32, 33
while, 3, 66, 70
wildcard pattern (.), 9, 28, 53, 72
wildcard pattern row (.,), 3, 9, 28, 30, 54, 72
with, 3, 8, 71
withtype, 3, 65, 67, 71

Y

Yield, 33
